16. ABSTRACT

A systemic approach for identifying potential safety countermeasures and implementing them across groups of locations sharing the same risk characteristics has been developed for pedestrian-vehicle collisions. This study was funded by the California Department of Transportation (Caltrans) to develop methods for identifying sites where there is potential for significant reductions in pedestrian and bicyclist injury. Data collected between 1998 and 2007 from a 16.5-mile section of San Pablo Avenue (SR 123) in the San Francisco East Bay was used as the study area. A database containing all useful crash information was developed and applied to study the spatial patterns, crash types, and location types of pedestrian-related collision. Several data stratifications were investigated to determine appropriate data aggregations for pedestrian safety analysis. Bicycle-related collisions were also included in the analysis to show the differences between pedestrian and bicycle collisions. A systemic approach was developed to identify the systemic hot spots in the transportation system and then recommend countermeasures for systemic implementation across a targeted type of facility.

Executive Summary

Urban arterials are different from most State Highway System (SHS) facilities; they have controlled intersections, divided multi-lanes, multimodal users, often with mixed land uses on both sides. This type of roadway comprises only 2% of the total miles in the California SHS, however it experiences 22% of SHS pedestrian injuries. Over the past decade, pedestrians accounted for approximately 12 percent of all traffic fatalities in the United States. Pedestrians and bicyclists are the most vulnerable road users (VRU) in all the crashes.

This study was funded by the California Department of Transportation (Caltrans) to develop methods for identifying sites where there is potential for significant reductions in pedestrian and bicyclist injury. To date, there are two approaches used by state agencies to allocate safety resources. One is the hotspot approach which focuses on identifying and recommending improvements for high collision concentration locations; the other is the systemic approach which seeks improvements that can be implemented at various sites across a network, based on specific roadway features that are associated with a particular crash type.

Systemic improvements generally have a lower per-site cost as they are implemented at multiple locations across a network. The systemic approach is a supplementary approach to the hot spot method. Using this approach, users can identify systemic hotspots which share the same high risk characteristics, and then recommend countermeasures for systemic implementation across groups of locations which may offer an economy of scale effect.

In this study, a systemic approach is developed to identify the appropriate blanket improvements along urban arterials across a targeted type of facility. Crashes along the study sites were counted for specific crash and facility type pairs. The data is assembled in a matrix which provides a snapshot of what types of crashes are occurring on what types of facilities and help in identifying the "systemic hotpsots". This approach provides guidance about the possible set of countermeasures that can be used to reduce the specific type of crashes for each facility type. This method uses data from Caltrans Accident Surveillance and Analysis System (TASAS) and bridges the gap between low data availability and the detailed information requirements of the existing countermeasure selection tool.

The study sites used in this report are a 16.5-mile section of San Pablo Avenue (SR 123), an arterial corridor in San Francisco's East Bay and a 4.9-mile section of Santa Monica Boulevard in Los Angeles County. A database including all VRU collisions was constructed using TASAS and SWITRS. The San Pablo Avenue Corridor is a system of freeways and major arterials serving the east shore of the San Francisco Bay, from downtown Oakland north to the City of Hercules, while the other study area is a major arterial in Southern California.

To allocate resources along urban arterials, the safety challenges of different types of sites need to be identified. Looking at all the data together may make it difficult to determine specific hazards at an intersection, or to identify the characteristics of certain types of collisions. Therefore, collision data should be stratified according to important and relevant attributes, such as crash outcome, location, environment, etc. Information found in crash data can help in identification of important stratifications. A stratification system is recommended in this study for categorizing pedestrian and bicyclist collisions since it was shown that pedestrian and bicycle crashes have different spatial distributions and are affected by different environmental features such as light and weather conditions. This stratification was used in developing the Pedestrian Systemic Monitoring Approach for Road Traffic Safety (PEDSMARTS).

The PEDSMARTS approach proposed in this study is a method to identify high collision concentration locations (HCCL) for pedestrians and bicyclists in order to develop strategies to direct resources toward reducing pedestrian and bicyclist injuries along urban arterials. The procedure to develop these strategies involves the following steps:

1. Estimate the number of crashes of specific crash type and at a specific type of facility
2. Present the data in a matrix to map the distribution of crashes types across all facility types
3. Identify the "systemic hotspots" in the matrix
4. Identify the corresponding the countermeasures for each cell to identify the which could be implemented for the specific crash type occurring at the specific location type
5. Select the appropriate countermeasure which can be implemented throughout all of the similar locations

To identify the crash type and crash location type related to the appropriate countermeasures, the required information is obtained from TASAS database. The available combinations of crash types, crash locations, and corresponding countermeasures are then listed.

It is recommended that PEDSMARTS method proposed in this study be developed into a comprehensive systemic pedestrian safety tool to be used across the State Highway System and provide recommendations for systemic improvements for pedestrian and bicycle safety.

1   Introduction

1.1   The Systemic Safety Approach

Over the past decade, pedestrians accounted for approximately 12 percent of all traffic fatalities in the United States, totaling more than 4,500 deaths per year. Worldwide, pedestrians suffer the largest share of the 1.2 million annual traffic fatalities. As people are being encouraged to walk more to reduce environmental impacts and improve public health, transportation professionals are obligated to make walking as safe as possible. Many of the risk factors and the spatio-temporal distributions of crashes that involve pedestrians are inherently different from crashes that only involve motorized vehicles. Moreover, potential safety improvements for pedestrians are typically dedicated solely for pedestrian safety applications (Bartlett 2012), meaning that many existing safety practices cannot be applied to improve pedestrian safety without significant modifications. Over 1,200,000 injuries took place in California, between 2006 to 2010 with a reduction rate of 18%. In the same period, the fatalities were 17,400 and from 2006 to 2010 the number has been reduced by 36%. But after 2010, the trend changed. From 2010 to 2011 the number of fatalities raised from 2,720 to 2,791. Pedestrians and bicyclists are the most vulnerable road users in all the crashes. They have the higher vulnerability than any other modes.

To date, there are two approaches used by state agencies to allocate safety resources. One is the hotspot approach which focuses on identifying and recommending improvements for high collision concentration locations, while the other is the systemic approach which seeks improvements that can be implemented at various sites across a network, based on specific roadway features that are associated with a particular crash type. Systemic improvements generally have a lower per-site cost as they are implemented at multiple locations across a network. Currently, the hotspot approach is the dominant funding mechanism for most state agencies in the United States. However, some agencies are increasing the proportion of funding allocated to systemic road safety improvements to complement the hotspot approach (Preston 2010).

The systemic approach is valuable for facilities that have relatively low crash frequencies (e.g., rural roads) and are therefore less likely to be identified as hotspots and subsequently considered for safety improvements. Similarly, pedestrian crashes exhibit lower crash frequencies and accordingly this approach results in few resources being allocated to conduct site investigations to improve pedestrian safety. In addition, pedestrian data is often missing essential elements (e.g., exposure) required for hotspot identification.

In light of this, there is an urgency to increase the knowledge base available to public agencies and others for identifying systemic prevention mechanisms for pedestrian fatalities and injuries.

1.2 Comparison of the PBCAT and SMART Approaches

What is the PBCAT Approach?
The Pedestrian and Bicycle Crash Analysis Tool (PBCAT) is a software which assists state and local pedestrian and bicycle coordinators, planners, and engineers in developing and analyzing crash databases. Based on the specific crash type, the software can select appropriate countermeasures to address the identified problem.

How Does PBCAT Work?
To develop the database, users need to read through the narratives, collision diagrams and descriptions in the collision reports from the police, and then enter the required details using the PBCAT software. Based on this detailed information, pedestrian crashes can be classified into 16 groups consisting of 56 unique types. The software then offers 49 countermeasures related to each of the 16 groups to recommend proper improvements for the identified collision type.

How does the SMART approach differ from PBCAT?
- The SMART approach is based on the information available in the TASAS database, from which PBCAT is incompatible.
- SMART is preferred for the systemic approach, while PBCAT is more effective for "case-by-case" investigation.
- SMART selects countermeasures based on infrastructure sharing the same safety risks and crash types, while PBCAT focuses solely on the crash type.
- SMART screens the infrastructures along the roadway system, including intersections, roadway segments, corridors or entire areas, while PBCAT focuses only on the intersections.

Variables	PBCAT	SMART
Data resource	Crash report	TASAS
Analysis resolution	Case level	Roadway system level
Components	Crash types	Risky locations and crash types
Facilities	Intersection	Intersection, roadway segment, corridor, area
Countermeasure generation	Spot	Systemic

2   Developing a Database Structure

2.2   Study Sites

San Pablo Avenue

The study area, shown in Figure 1 is a 16.5-mile section of San Pablo Avenue (SR 123), an arterial corridor in San Francisco's East Bay. Some features are listed below:

- The corridor runs from Frank H. Ogawa Plaza (red arrow on right) in downtown Oakland to Solano Avenue in Richmond (red arrow on left).
- It passes through 5 cities: Oakland, Berkeley, Albany, El Cerrito, and Richmond.
- It crosses 180 intersections that are on average approximately 484 feet (0.09 miles) apart.
- It intersects with six major Vulnerable Road User (VRU) arterials—arterials with high levels of pedestrians and bicyclists: 17th Street and 40th/Adeline Streets (Oakland), Ashby Avenue (Oakland-Berkeley border), University Avenue (Berkeley), Solano Avenue and Hill St. (El Cerrito).
- The environment along this corridor varies significantly as it moves through different cities and land-use characteristics, e.g., mega-retailers at Hill Street in Richmond, local retail at Solano Avenue in El Cerrito, at University Avenue in Berkeley, at Ashby and at 40th/Adeline Streets in Oakland, and a compact downtown business district at 17th Street in Oakland. Appendix 1 shows photos of the intersections with the major VRU arterials.
- The corridor was the site of 413 VRU (pedestrian and bicyclist) collisions between 1998 and 2007, which corresponds to an annual collision rate of about 0.23 collisions per intersection. In the figure, circles indicate collision locations.

(a)
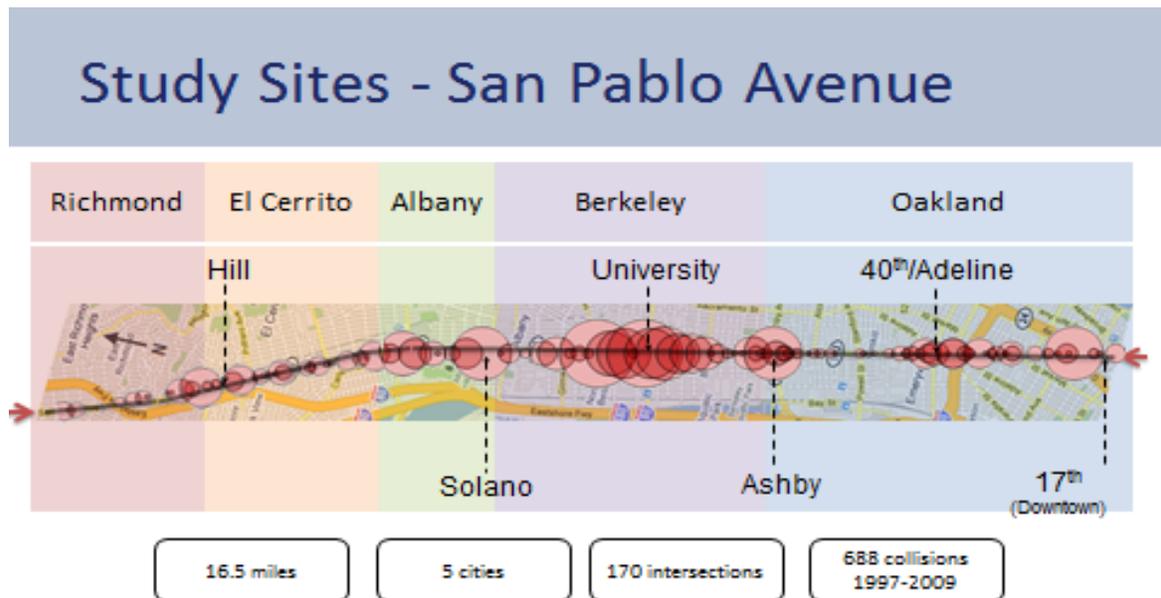

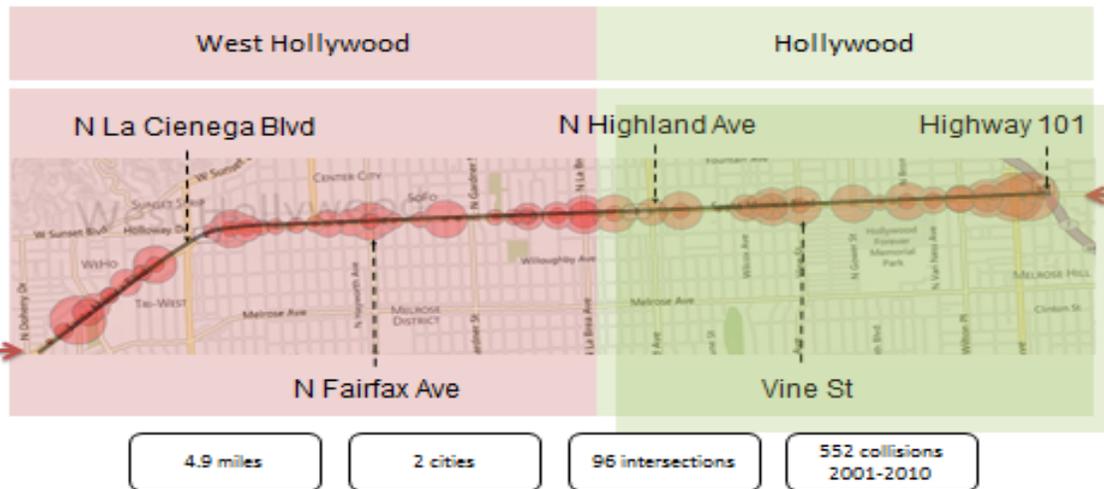

(b)

Figure 1. Cities, VRU Arterials, and VRU Crashes in the study sites: (a) San Pablo Avenue, (b) Santa Monica Blvd

A database including all VRU collisions was constructed using the Statewide Integrated Traffic Records System (SWITRS) maintained by the California Highway Patrol (CHP). The database includes all pedestrian and bicyclist collisions that occurred between 1998 and 2007. Each collision was geocoded and matched to the closest intersection. The running distance from the first intersection through the last one was also calculated.

The red circles in Figure 1 represent the relative number of collisions for each intersection, with larger circles indicating higher numbers of crashes.

This figure illustrates (i) that there is a high concentration of collisions at some intersections, and (ii) that there is a high concentration within groups of intersections, suggesting there are factors affecting not just an individual intersection, but an entire set of intersections. The first observation would suggest that resources be directed at individual intersections with the highest number of collisions. The second observation would suggest that there is value in extending this approach to clusters of intersections that experience a high number of collisions. In the following sections, we examine these and other approaches for their usefulness in identifying methods for choosing treatments for VRU safety.

Santa Monica Blvd
The study area, shown in Figure 1 (b) is a Santa Monica Blvd across the City of West Hollywood and the City of Los Angeles from west to east, Los Angeles County,

California. It starts from the intersection of Santa Monica Blvd and N Doheny Dr in the west to the intersection of Santa Monica Blvd and Highway 101 On Ramp in the east. Crashes took places on Santa Monica Blvd are defined as crashes located within a 30 feet both-side buffer zone generated by "Buffer" tools in ArcGIS 10 using road lines of Santa Monica Blvd. Intersection points are generated from Santa Monica Blvd and its cross roads in the study scale. There are 552 vulnerable road user crashes extracted out and 96 intersections generated for analysis.

3   Stratification Analysis

This section evaluates the strengths and weaknesses of studying individual intersections using a single year as the sampling period. Table 1 summarizes the distribution of the frequency of VRU collisions per intersection for each of the 10 years, ranging from the percentage of intersections with zero (0) collisions to the percentage of intersections which experienced four (4), the greatest number of VRU collisions at any one intersection during this time period.

Urban arterials are different from most state highway system (SHS) facilities. They have controlled intersections, divided multi-lanes, multimodal users, and mixed land use on both sides. This type of roadway comprises only two percent of the total miles in the SHS, however it experiences 22 percent of SHS pedestrian injuries. Urban arterials require special attention for the modes of walking and bicycling.

To allocate resources along urban arterials, the safety problems affecting the most dangerous intersections should be identified. Putting all the data together may make it difficult to determine specific hazards at an intersection, or to identify the characteristics of certain types of collisions. Therefore, collision data should be stratified according to important and relevant feature categories, such as crash outcome, location, environment, etc.

3.1   Information Found in TASAS Crash Data

Caltrans uses the Traffic Accident Surveillance and Analysis System (TASAS) database. Information found in this crash database can help in identification of important stratifications. As shown in Table 1 and Table 2, non-fatal crashes are more likely to occur during daylight hours, while fatal injuries are more likely to occur during nighttime hours. In addition, non-fatal crashes are more likely to occur while pedestrians are crossing at intersections, while fatal injuries are more likely to occur while pedestrians are crossing at a non-crosswalk location. These are examples of how injury severity and distance from intersection can be important stratifications in crash data.

Table 1. Pedestrian Crashes at Urban Arterials Under Different Light Conditions

Light condition	Non-fatal injuries	Fatal injuries	All injuries
Daylight	1057	51	1108
Dusk-dawn	64	2	66
Dark – street lights	623	91	714
Dark – no street lights	40	18	58
Dark – street lights not functioning	5	3	8
(blank)	14	0	14
Total	**1803**	**165**	**1968**

Source: TASAS 2005-

Table 2. Pedestrian Crashes at Urban Arterials with Different Pedestrian Movements

Pedestrain movement	Non-fatal injuries	Fatal injuries	All injuries
⊞ Crossing in crosswalk at Intersection	1001	50	1051
⊞ Crossing - not in crosswalk	446	84	530
⊞ In roadway - include shoulder	154	18	172
⊞ Not in Roadway	119	7	126
⊞ Crossing in crosswalk not at Intersection	26	0	26
⊞ Other	57	6	63
Total	1803	165	1968

Source: TASAS 2005-

Driver behavior may differ before and after a car passes through intersection. Upstream of an intersection, as a car approaches the intersection, the driver likely expects a stop and slows down, perhaps paying more attention to pedestrians. But when the car leaves an intersection, the driver is likely to speed up, perhaps paying less attention to the environment. Crash location—upstream or downstream of an intersection—can be an important stratification in crash data.

3.2 Technique

Different transportation modes can be identified by selecting the fields of "Ped" or "Bike" in the database. In addition, crashes of various severity levels can also be obtained from the database in the corresponding fields.

Technique to Determine the Distance Threshold
To stratify collision data by their proximity to the intersections, a distance threshold is required. To obtain this threshold, the size of intersections and the distance from collisions to their closest intersection are analyzed. Figure 2 shows the histogram of the distance from intersection center to the inner side of the crosswalk. As shown in the figure, at 95% of intersections, the crosswalks are located within 50 feet from the center of intersection.
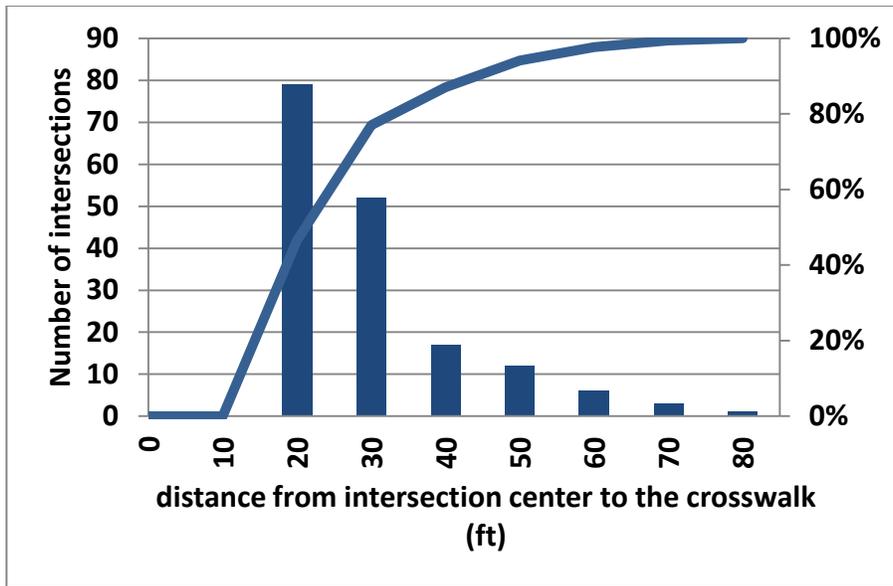

Figure 2. Histogram of Distance from Intersection Center to the Crosswalk

Figure 3 illustrates the histogram of distances from crashes to their closest intersections. Based on this distribution, 50 percent of pedestrian crashes occurred within the range of 50 feet and 50 percent of bicycle crashes occurred within the range of 40 feet. Based on this distribution, 50 feet is designated as the threshold of the stratification. This threshold not only reflects the distribution of collisions relative to intersections, but also can reflect the size of the intersections.
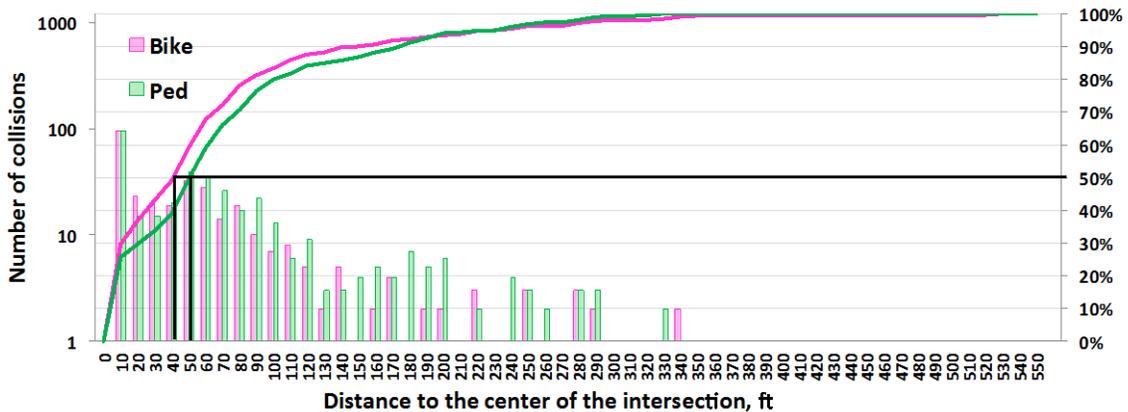

(a)
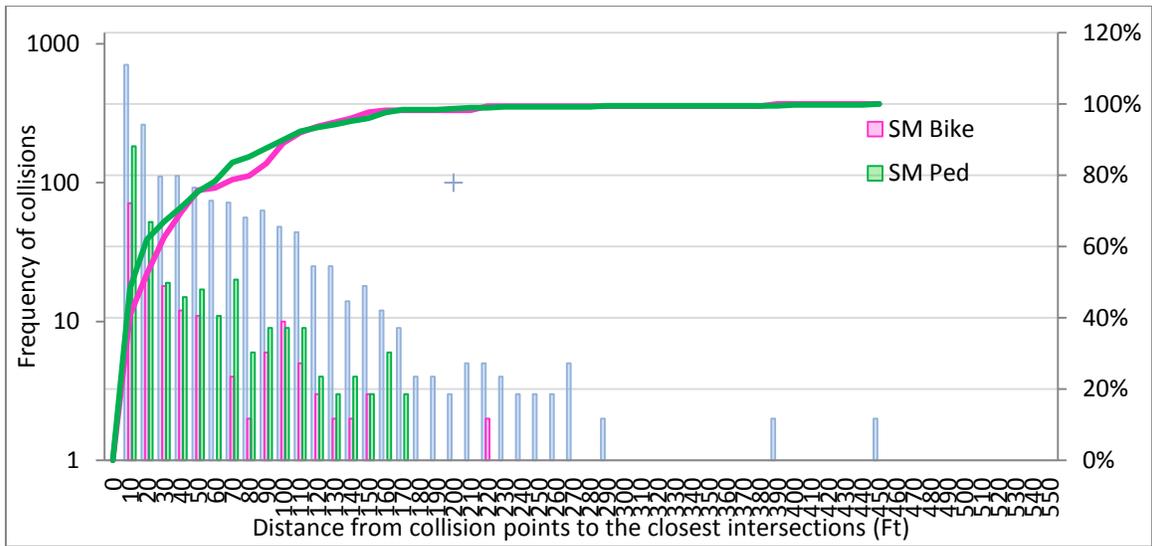

(b)

Figure 3. Histogram of Distance from Crashes to Their Closest Intersection Center: (a) San Pablo Ave, (b) Santa Monica Blvd

Technique to Identify Upstream or Downstream Location of Collision

The information regarding whether a collision happened upstream or downstream of an intersection is not provided. Therefore, it is necessary to identify this factor and create a field code to represent it in the database. Figure 4 shows an example of four crash points at an intersection. To determine whether a crash occurred upstream or downstream, it is first necessary to determine on which side of the intersection the crash occurred, in addition to the direction of traffic direction. For example, in the figure, the crash shown in the upper right is on the north side of the intersection and heading north, meaning that it is downstream of the intersection.

16

Figure 4. Example of Identification of Upstream and Downstream Crashes

Based on this example, two kinds of data are required to determine the relative position and traffic direction. The first is the post-mile data of crashes and intersections, which can be compared to identify the relative position of crashes to their closest intersections. The second is the direction of the traffic flow. The post-mile and traffic direction data for each collision can be found in the collision database, while the post-mile data for intersection can be found in infrastructure database. After the relative position and traffic direction have been identified, it is easy to determine whether the crash happened upstream or downstream of the intersection. Figure 5 demonstrates this technique using data from San Pablo Avenue as an example. Applying this technique, a field for upstream or downstream location can be added to the collision database.

Figure 5. Technique to Identify Upstream and Downstream Crashes

3.3 Identifying Stratifications

Based on information found in the crash data, stratifications can be identified. As shown in Table 3, different traffic modes (e.g., walking and bicycling) can be identified, and collision data can be stratified into various categories (e.g., spatial related stratification or outcome related stratification). For analysis, comparisons can be made between characteristics of the same traffic mode for different stratifications (SMDS), or between different traffic modes for the same stratification (DMSS), as shown in Table 3.

Table 3. Stratification Pairs

| Stratifications / Modes	Spatial Related Stratification				Outcome Related Stratification	
	Distance from crash to intersection		Upstream or downstream of an intersection		Severity level	
	Within 50 ft.	Over 50 ft.	Upstream	Downstream	Fatal/severe	Minor/moderate
Ped	SMDS	SMDS	SMDS	SMDS	SMDS	SMDS
Bike						
Ped	DMSS		DMSS		DMSS	
Bike	DMSS		DMSS		DMSS	

3.4   Spatial Pattern Evaluation

Spatial Distribution

Analysis will determine whether one type of collision is more aggregated than another type. If one type of collision is more aggregated than another, it means this type of collision is more clustered at several intersections instead of evenly distributed across along the urban arterial.

Method

To quantify the degree of aggregation, the Lloyd Patchiness Index (PI) is calculated for collision data. As shown in Figure 6, if PI is bigger than 1, this indicates an aggregated distribution. If PI is equal to 1, this indicates a random distribution. If PI is smaller than 1, this indicates a regular distribution. A larger PI value indicates a higher degree of aggregation. When this index is calculated for collision data along urban arterial, it quantifies how the collisions are distributed across intersections.

Regular	Random	Aggregated
PI <1	PI =1	PI >1
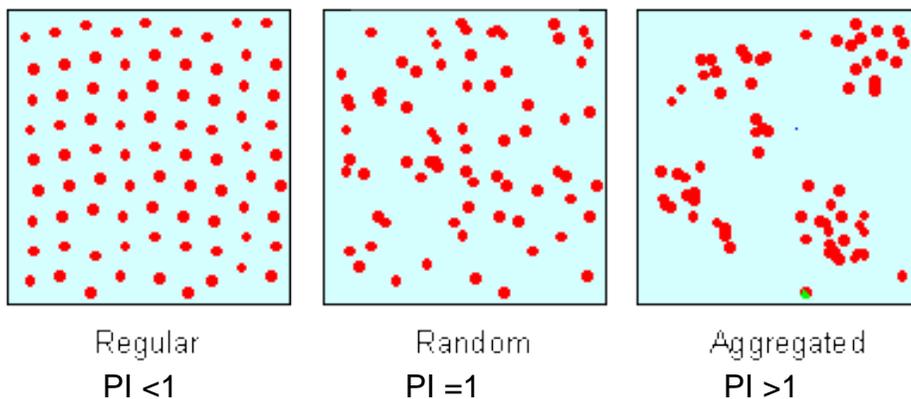

Figure 6. Relationship Between PI Value and Distribution Pattern

Taking pedestrian and bicycle collision data from San Pablo Avenue and Santa Monica Blvd asexamples, the PI values are calculated, and PI values are shown from lowest (dark green) to highest (red) as presented in Table 4.

Table 4. Patchiness Index for Different Crash Types, San Pablo Avenue and Santa Monica Blvd

San Pablo Ave		
	Pedestrians	Bicyclists
Within 50 ft.	2.38	1.8
Over 50 ft.	3.6	2.69
Upstream	3.34	2.4
Downstream	2.8	2.76
Fatal/Severe	1.84	2.01
Minor/Moderate	2.47	1.96
Santa Monica Blvd		
	Pedestrians	Bicyclists
within 50ft	2.13	1.51
over 50ft	2.22	2.07
fatality and severe	1.79	0
visable injury and complain of pains	1.88	1.42

Result

Based on the results, three conclusions can be made. First, pedestrian and bicycle collisions are distributed at different aggregation level in the same stratification. For example, pedestrian collisions within 50 feet of an intersection are more aggregated than bicycle collisions within the same stratification. Second, even the same traffic mode may experience different distribution patterns under different stratifications. For example, pedestrian collisions that occurred within 50 feet of an intersection are less aggregated than those that occurred over 50 feet from an intersection. Third, pedestrian collisions are more aggregated than bicycle collisions under each stratification method.

Two observations could be noted. First, for the stratification of downstream collision, the difference between pedestrian and bicycle collisions is not significant. The same is true for the stratifications of fatal and severe collisions. This indicates that pedestrian and bicycle collisions can be combined for analysis under the stratification of downstream collisions or fatal and severe collisions. Second, the difference between bicycle collisions under fatal/severe and minor/moderate stratifications is not significant, suggesting that it may not be necessary to separate bicycle collisions by different severity levels.

3.5 Spatial Consistency

Next step is to analyze the special consistency. The first question is whether the danger levels for pedestrian and bicyclists are the same at each intersection. Using Figure 7 as an example, the top map shows pedestrian collisions, and the bottom map shows bicycle collisions, and each red bubble represents an intersection along an arterial. The larger the

size of the bubble shown on the map indicates a higher level of danger. The largest concentration of collisions shown on the pedestrian collision map is not at the same location as the largest concentration of bicycle collisions, indicating that the most dangerous intersections differ for pedestrians and bicyclists.

Figure 7. Example of Danger Level Consistency

The second question is whether each intersection contributes the same number of pedestrian and bicyclist collisions. Referring to Figure 8 as an example, the bubbles shown in the chart represent intersections. The x axis shows the number of pedestrian collisions that occurred at that intersection, and the y axis shows the number of bicycle collisions at the same intersection. If an intersection experiences the same number of pedestrian and bicyclist collisions, the bubble will appear on the line of x=y. These two figures can be used to check the spatial consistency of collisions.
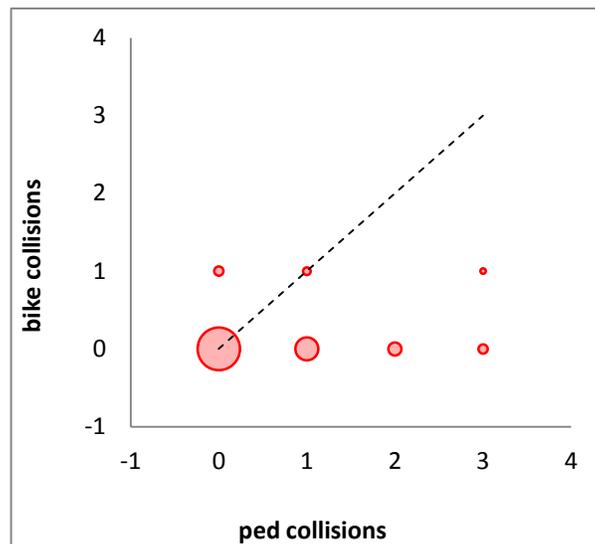

Figure 8. Example of Crash Number Consistency

Method
The following are the steps to develop the figures illustrated above:

Step 1: Cluster collisions at their closest intersection
Step 2: List intersection ID and its collision count
Step 3: Display intersection points on map, using size of points to show number of collisions
Step 4: Conduct the Pearson Chi Square test for the two groups of data in a comparison
Step 5: Create a bubble chart of intersections, using the number of pedestrian and bicyclist collisions as x and y axis, and the number of intersections to determine the bubble size.

Results
Using collision data on San Pablo Avenue and Santa Monica Boulevard as examples, the spatial consistency can be checked using the above method. Different traffic modes for the same stratifications are analyzed, as shown in appendix 2. The danger levels of intersections are different for pedestrians and bicyclists. In addition, most of the intersections do not experience the same number of pedestrian and bicyclist collisions. This analysis can also be applied to the same transportation mode for different stratifications.

The P values for the Pearson Chi Square test are shown in Table 5, which demonstrates that the differences between pedestrian and bicyclist collisions for the same stratification are significant at the 95 percent confidence level (except the stratification of fatal/severe collisions, perhaps due to the small sample size for this data. The P values for pedestrian collisions for different stratifications are all smaller than 0.05, indicating that the difference between the comparisons is significant. The differences between bicycle collisions for different stratifications are also significant, except for the stratification of distance to intersections, which means that bicycle collisions occurring within 50 feet of an intersection or beyond 50 feet from an intersection can be combined for analysis.

Table 5. P-values of Pearson Chi Square Test to Check Difference between Same Modes with Different Stratification or Between Different Modes with Same Stratification

Spatial Consistency for San Pablo Avenue (Statistical Significance)			
	Peds/Bike	**Peds**	**Bike**
Within 50ft	0.00	0.00	0.31
Over 50ft	0.00		
Upstream	0.00	0.00	0.00
Downstream	0.00		
Fatal/Severe	0.07	0.00	0.00
Minor/Moderate	0.00		

Spatial Consistency for Santa Monica Blvd. (Statistical Significance)			
	Peds/Bike	**Peds**	**Bike**
Within 50ft	0.00	0.00	0.00
Over 50ft	0.00		
Upstream	0.00		
Downstream	0.00		
Fatal/Severe	0.31	0.00	0.00
Minor/Moderate	0.02		

In summary a stratification system is recommended for categorizing pedestrian and bicyclist collisions, by which different traffic mode collisions can be stratified according to their spatial and outcome related features, and by environmental features such as light and weather conditions.

Data can be stratified if the characteristics differ. Pattern evaluation can be used to test the difference between stratifications to determine whether collisions should be separated during analysis. Two spatial pattern evaluations were discussed: spatial distribution and spatial consistency.

4 Pedestrian Systemic Monitoring Approach for Road Traffic Safety (PEDSMARTS)

The proposed PEDSMARTS approach is a method to identify high collision concentration locations (HCCL) for pedestrians and bicyclists in order to develop strategies to direct resources toward reducing pedestrian and bicyclist injuries along urban arterials.

4.1 Procedure

The procedure to develop these strategies involves the following steps:

1. Count the number of crashes of specific crash type and at a specific type of facility
2. Insert the numbers into a matrix to map the distribution of crashes across all infrastructures (Figure 9)
3. Identify systemic hot spot in the matrix
4. Identify the corresponding cell in the countermeasure matrix (Figure 10) to identify the potential countermeasures which could be implemented for the specific crash type occurring at the specific location type
5. From the countermeasures included in the list (Figure 11), select the appropriate countermeasure which can be implemented throughout all similar locations

4.2 Matrix introduction
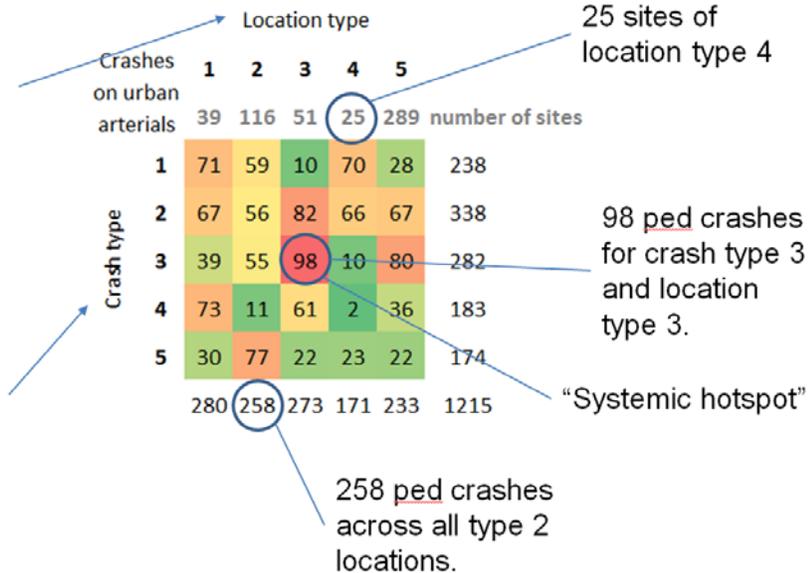

Systemic Hot Spot Identification Matrix

The systemic hot spot identification matrix is developed based on crash and location types for the selected sites. Figure 9 presents an example for systemic hot spot identification matrix on urban arterials. As shown in the figure, locations are classified into five types based on site features (e.g., intersection or mid-block, ADT, speed, number of lanes, traffic control method, etc.), and the crashes are classified into five types based on crash features (e.g., pedestrian and turning vehicle crashes, speeding, etc.). The number of sites for each location type is summarized in the second row. For example, there are 25 sites for location type 4. The value in each cell (x_{ij}) represents the number of type i crashes that occurred at location j. The values in the matrix are highlighted in different colors. The red cells represent the largest number of crashes, while the green cells represent the smallest number of crashes. The total number of crashes for each location type is summarized in the last row and the total number of crashes for each crash type is summarized in the last column. For example, there are 258 pedestrian crashes across all type 2 locations. Based on the data collected at selected sites, the cell with the largest number of crashes is identified as the "systemic hotspot." In the example shown, the cell for crash type 3 and location type 3 with 98 crashes is identified as the systemic hotspot.

Location type is based on features of the site.
Example:
Intersection; ADT<10,000; Speed<= 45 mph; 3 or 4 lanes; Traffic Signal Not present.

Crash type is based on features of the crash.
Example:
Turning vehicle

25 sites of location type 4

98 ped crashes for crash type 3 and location type 3.

"Systemic hotspot"

258 ped crashes across all type 2 locations.

Crashes on urban arterials	Location type					
	1	2	3	4	5	number of sites
	39	116	51	25	289	
Crash type 1	71	59	10	70	28	238
2	67	56	82	66	67	338
3	39	55	98	10	80	282
4	73	11	61	2	36	183
5	30	77	22	23	22	174
	280	258	273	171	233	1215

Figure 9. Example of the Systemic Hot Spot Identification Matrix
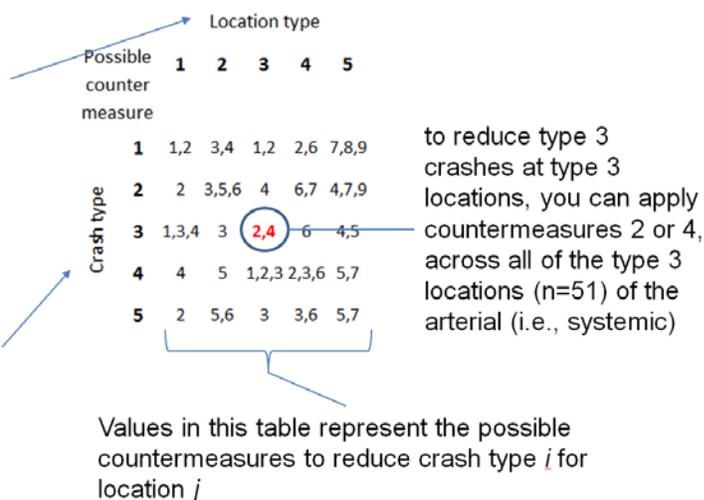

Systemic Countermeasure Matrix

The systemic countermeasure matrix is also established based on the crash type and location type described above. As shown in Figure 10, values in each cell (y_{ij}) represent potential countermeasures to reduce crash type i for location j. For example, to reduce type 3 crashes at type 3 locations, which were identified as "systemic hotspots" in the previous section, transportation engineers can implement countermeasure 2 or 4, across all type 3 locations (n=51) along the arterial. The detailed attributes for each countermeasure are discussed in the following section.

Location type is based on features of the site.
Example:
Intersection; ADT<10,000; Speed<= 45 mph; 3 or 4 lanes; Traffic Signal Not present.

Crash type is based on features of the crash.
Example:
Turning vehicle

to reduce type 3 crashes at type 3 locations, you can apply countermeasures 2 or 4, across all of the type 3 locations (n=51) of the arterial (i.e., systemic)

Possible counter measure	Location type				
	1	2	3	4	5
Crash type 1	1,2	3,4	1,2	2,6	7,8,9
2	2	3,5,6	4	6,7	4,7,9
3	1,3,4	3	2,4	6	4,5
4	4	5	1,2,3	2,3,6	5,7
5	2	5,6	3	3,6	5,7

Values in this table represent the possible countermeasures to reduce crash type i for location j

Figure 10. The Systemic Countermeasure Matrix

Countermeasure List

The countermeasure list provides a detailed description of the possible countermeasures to reduce pedestrian crashes at the selected sites, as shown in Figure 11. The attributes for each countermeasure include the cost and Crash Modification Factors (CMF) for various types of crashes. The Crash Modification Factors can be used to calculate the potential benefits associated with each countermeasure. Based on the benefit-cost analysis, decision makers can identify preferred countermeasures to implement at selected sites.

Figure 11. The Countermeasure List

4.3   Crash Type and Crash Location Classification

In the systemic hot spot identification matrix, crashes and roadway facilities must be classified to correspond to available data, and must also be useful for selecting appropriate countermeasures. Therefore, the research is initiated from two opposite directions. The first is from the recommended countermeasures. From this direction, the appropriate countermeasure to reduce a specific type of crash at a specific type of location can be identified, and the relationships between crash types, facility types, and countermeasures can be determined. Based on this, the corresponding countermeasure matrix can be developed. The second direction is from the existing database. From this direction, useful information to identify crash and facility types is available, from which appropriate countermeasures can be selected. Based on this, the systemic hot spot identification matrix can be developed.

Crash type and Crash Location Information from Countermeasures in PBCAT and Local Manual

The *Local Roadway Safety-a Manual for California's Local Road Owners* was developed to provide an easy-to-use, straightforward, comprehensive framework of the steps and analysis tools needed to identify locations with roadway safety issues and the appropriate

countermeasures (SafeTREC, 2012). In this manual, different recommended countermeasures are listed, with detailed descriptions and guidelines for implementation.

Based on this manual, the pedestrian safety countermeasures and their associated crash types and location characteristics are listed in Table 6. In addition to the local manual, the *Pedestrian and Bicycle Crash Analysis Tool Version 2.0* guide book was also reviewed. This software develops and analyzes the database containing details associated with crashes between motor vehicles and pedestrians or bicyclists. It uses this data to produce reports and select countermeasures to address the problems identified (David L. Harkey, 2006). In this manual, 49 countermeasures related to pedestrian safety are described in detail regarding purpose, considerations, estimated cost, and case studies. Based on this manual, supplementary information was added to Table 6. In this table, each row represents the specific roadway facility characteristics, the related crash type and the corresponding countermeasure. The crash locations can be classified into two large groups: intersection and roadway segment.

Table 6. The Relationship between Crash Type/Location and Countermeasures

Crash Location			Crash Type	Countermeasures
Signalized	Marked Crosswalk	Indicator or not	Single vehicle involved	Install Pedestrian countdown signal heads
Signalized	Marked Crosswalk	High ped/bike volume	Speeding	Install advanced stop bar before crosswalk
Signalized	Unmarked crosswalk	No ped sig head, high vehicle turning movements	Ped vs. Turning vehicle	Install Pedestrian countdown signal heads or install crosswalk
Signalized	Marked/ unmarked	Freeway/arterial interx, high vehicle volume, high speed, or rail tracks	All	Install ped overpass/underpass
Signalized	Marked/ unmarked	Limited sight distance, pedestrian interaction	Ped vs. Right turn vehicle	Right turn on red restrictions
Signalized	Marked/ unmarked	High ped volume	All	Pedestrian-only or pedestrian-lead phase
Signalized	Marked/ unmarked		All	Information signs on ped push buttons
Signalized	Marked/ unmarked		All	Push button functioning indicator
Un-signalized	Unmarked	High vehicle volume, school zone, left/right turn pocket	All	Install crosswalk (signs and markings)
Un-signalized	Marked/ unmarked	Long crossing distance	Speeding, light condition	Install raised medians/refuge island
Un-signalized	Marked/ unmarked	High ped volume	All	Install signal with ped. Signal
Un-signalized	Marked	High traffic volume, school zone, turns pockets	All	Install enhanced ped safety features
Un-signalized	Marked/ unmarked	Parking lane, low vehicle speed	Multi threat	Curb extension
Un-signalized	Marked/ unmarked	Intersections where volumes do not warrant a stop sign or a signal and intersection of two local streets	High speed intersections	Mini-circles

Crash Location			Crash Type	Countermeasures
Signalized and Un-signalized	Marked	Motor vehicle flows up to 1000 vehicles per hour, and with two-lane approaches	All	Advance stop lines
Signalized and Un-signalized	Marked/ unmarked	More night time crossing or downtown area	Light condition	Roadway lighting improvement
Signalized and Un-signalized	Marked/ unmarked	Bus stop on near side of intx or crosswalk	Bus related, crossing street form behind a bus	Transit stop treatment
Signalized and Un-signalized	Marked/ unmarked		Ped vs right turn vehicle	Improve right turn split
Signalized and Un-signalized	Marked/ unmarked	High conflict traffic (left turns)	Angle collisions	Roundabouts
Signalized and Un-signalized	Marked/ unmarked		Ped vs right turn vehicle	Curb radius reduction
Signalized and Un-signalized	Marked/ unmarked		High speed intersections	Intersection median barriers
Signalized and Un-signalized	Marked/ unmarked		High speed intersections	Raised intersections/raised median crossing
Signalized and Un-signalized	Marked/ unmarked	People who use wheelchairs	Ped vs right turn vehicle	Install curb ramps
Signalized and Un-signalized	Marked/ unmarked		Ped vs right turn vehicle	Curb radius reduction
T-interx	Marked/ unmarked	T-intersections on lower-volume streets in residential areas	All	Modified T-interx
No controlled crossing for a long distance along the roadway, mid-block, and or multi-lane urban road			Crossing crashes, ped visibility	Install ped crossings ,with signs and markings, signals
No bike lanes			Bike vs vehicle	Install bike lanes
High speed, high vehicular traffic			Trapped/ multi-car involved	Install raised medians/refuge island
No or not adequate sidewalks			Walking along roadway	Install sidewalk/walkway
Lower speed roadways, high vehicle volume			Crossing crashes, ped visibility	Install raised pedestrian crossing

Crash Location			Crash Type	Countermeasures
Night ped volume, commercial area, night time crossing volume			Pedestrian visibility	Roadway lighting improvement
Long crossing distance	Marked/ unmarked	Lower speed roadways	Multi-threat, dash/dart-out	Curb extension
Downtown area, two way roadways			Crossing crashes	Convert two-way to one way street
High speed, business area, one way roadway			Crossing crashes	Convert one-way to two-way street
Bus stop on the near side of the crosswalk			Bus related	Bus stop treatment
Long crossing distance, multi-lane urban road			Crossing crashes	Lane reduction
Freeway/arterial, high vehicle volume, high speed, or rail tracks			Speeding	Install ped overpass/underpass
High speed roads			Speeding	Road narrowing
Commercial districts			All	Street furniture/walking environment
Roadways with high number of driveways and parking			Right turning vehicles, ped visibility	Driveway improvement
Wide roadway			Speeding	Chokers
High speed, low vehicular traffic			Speeding	Chicanes, speed humps, speed table
Entering a commercial, residential, or business district			Speeding	Gate ways
Commercial, residential, or business district			Speeding	Landscaping
Commercial, residential, or business district			Speeding	Specific paving treatment
Commercial, residential, or business district			Speeding	Serpentine design
Commercial, residential, or business district			Speeding	Woonerf
On the roadside or on mast arms over midblock pedestrian crossings Marked			All	Ped hybrid beacon

TASAS Database

Caltrans uses the Traffic Accident Surveillance and Analysis System (TASAS) database. It is a sophisticated version of an electronic data processing (EDP) traffic records system. It includes an accident data base (AXDB), linked to a highway data base (HDB) which contains description elements of highway segments, intersections and ramps, access control, traffic volumes and other data. The database is used by Caltrans and also provides roadway and/or accident information for other associated state and local agencies (Caltrans, 2013). Based on the TASAS database, all the data information required for crash type and location type are listed in Table 6. The data availability for location characteristics is listed in Table 7, in which the first column identifies the two types of facilities: intersections and roadway segments. The second column lists the detailed characteristics for countermeasure selection. The third column indicates the availability of each specific characteristic in the TASAS database. In Table 8, the crash type information necessary for countermeasure selection and availability in the TASAS database are summarized. From these two tables, it is evident that not all the information necessary for countermeasure selection is available in the TASAS databese. To customize the systemic tool for the user, only the crash and location types which *can* be identified based on TASAS database are listed.

Table 7. Crash Location Data Availability in TASAS Database

	Location Description	TASAS Availability
Intersection	Signalized/unsignalized	Y
	Marked/unmarked	N
	T-intersection	Y
	Pedestrian indicator	N
	Pedestrian sig head	N
	Vehicle turning volume	N
	Pedestrian night crossing volume	N
	Area type	N
	Pedestrian volume	N
	Bicycle volume	N
	Bus stop near side of the crosswalk	N
	Long crossing distance	Y
	Freeway intersection	Y
	Vehicle volume	Y
	Vehicle speed	Y
	School zone	N
	Left turn pocket	N
	Right turn pocket	N
	Parking lane	N
	Stop sign	N
	Sight distance	N
	Number of lanes	Y
	People using wheel chairs	N

	Location Description	TASAS Availability
Roadway	Crosswalk along the roadway	N
	Crossing distance along the roadway	N
	Mid-block crosswalk	N
	Multi-lane	Y
	Urban road	Y
	Bike lane	N
	Speed	Y
	Vehicle volume	Y
	Sidewalk	N
	Commercial area	N
	Night time pedestrian crossing volume	N
	Crossing distance	Y
	Marked/unmarked	N
	Downtown area	N
	One way or two way	N
	Business area	N
	Bus stop on the near side of the crosswalk	N

Table 8. Crash Type Data Availability in TASAS Database

Crash type Description	TASAS Availability
Single vehicle involved	Y
Pedestrian vs turning vehicle	Y
Light condition	Y
Speeding	Y
Bus related	Y
Crossing street from behind the bus	N
Multi threat	N
Pedestrian vs right turn vehicle	Y
Angle collision	Y
Crossing crashes	Y
Pedestrian visibility	N
Driver visibility	Y
Dash/dart	N
Bicycle vs vehicle	Y

Available Classifications of Crash Type and Crash Location
Based on the data available in the TASAS database and the information required for countermeasure selection, the crash type and crash location type are listed in Table 9.

Table 9. Available Information in TASAS Database

Crash type		Single vehicle involved
		Ped vs turning veh
		Light condition
		Speeding
		Bus related
		Ped vs right turn veh
		Angle collision
		Crossing crashes
		Driver visibility
		Bike vs. Veh
Crash location	Intersection	Signalized/un-signalized
		T-intersection/regular intersection
		Long crossing distance
		Freeway/arterial intersection
		Vehicle volume
		Vehicle speed
		No of lanes
	Roadway segment	Multi-lane
		Urban road
		Vehicle speed
		Vehicle volume
		Crossing distance

As discussed below, Table 10 lists all the available combinations of crash types, crash locations, and corresponding countermeasures. Appendix 2 illustrates the matching process in which the data not available in TASAS are shown in gray, while available data are shown in black.

**Table 10. Usable Combination of Crash Types, Crash Locations,
and Corresponding Countermeasures**

	Crash Location			Crash Type	Countermeasures
Intersections	Signalized	Marked/ unmarked	Freeway/arterial interx, high vehicle volume, high speed, or rail tracks	All	Install ped overpass/underpass
	Signalized	Marked/ unmarked		All	Information signs on ped push buttons
	Signalized	Marked /unmarked		All	Push button functioning indicator
	Un-signalized	Marked/ unmarked	Long crossing distance	Speeding, light condition	Install raised medians/refuge island
	Un-signalized	Marked/ unmarked	Intersections where volumes do not warrant a stop sign or a signal and intersection of two local streets	High speed intersections	Mini-circles
	Signalized and un-signalized	Marked/ unmarked		Ped vs right turn vehicle	Improve right turn split
	Signalized and un-signalized	Marked/ unmarked		Ped vs right turn vehicle	Curb radius reduction
	Signalized and un-signalized	Marked/ unmarked		High speed intersections	Intersection median barriers
	Signalized and un-signalized	Marked /unmarked		High speed intersections	Raised intersections/raised median crossing
	Signalized and un-signalized	Marked/ unmarked		Ped vs right turn vehicle	Curb radius reduction
Roadway segment	Long crossing distance, multi-lane urban road			Crossing crashes	Lane reduction
	Freeway/arterial, high vehicle volume, high speed, or rail tracks			Speeding	Install ped overpass/underpass
	High speed roads			Speeding	Road narrowing
	Wide roadway			Speeding	Chokers
	High speed, low vehicular traffic			Speeding	Chicanes, speed humps, speed table

Identifying the crash types and crash locations

Based on Table 10, the crash types could be the combination of the types below:
1. Speeding or not
2. Light condition or not
3. Pedestrian vs. right turn vehicles or not
4. Crossing crashes or not

The crash location types could be the combination of the types below:
1. Signalized intersection or not
2. Wide road or not
3. Arterial road or not
4. High speed road or not
5. High volume road or not
6. Multi-lane road or not

Before developing the matrix, it should be determined whether the location type can divide the system into separate groups. For example, if the target is a corridor in an urban area, and all the road segments on it are multi-lane and arterial, then the two types "multi-lane or not" and "arterial road or not" are not effective for separating the road segments.

The location groups for roadway segment are:
- Road segments with speed limit higher than 35 mph and narrow
- Road segments with speed limit higher than 35 mph and wide
- Road segments with speed limit lower than 35 mph and narrow
- Road segments with speed limit lower than 35 mph and wide

The location groups for intersection are:
- Un-signalized intersection with speed limit higher than 35 mph and narrow
- Un-signalized intersection with speed limit higher than 35 mph and wide
- Un-signalized intersection with speed limit lower than 35 mph and narrow
- Un-signalized intersection with speed limit lower than 35 mph and wide
- Signalized intersection with speed limit higher than 35 mph and narrow
- Signalized intersection with speed limit higher than 35 mph and wide
- Signalized intersection with speed limit lower than 35 mph and narrow
- Signalized intersection with speed limit lower than 35 mph and wide

4.4 Case Study

PEDSMARTS was applied to pedestrian systemic safety analysis for San Pablo Ave in California, from the intersection of Cutting Blvd. and San Pablo Ave. to the intersection of 35th St. and San Pablo Ave. The study section is comprised of 127 intersections and 30 road segments recorded in the TASAS database. There were 160 pedestrian collisions that occurred along this section of the roadway from 2002 to 2009, 67 of which occurred at intersections and 93 at road segments.

Step 1—Identifying crash types and location types

Based on the method introduced in previous section, the first step is to check the database and determine the feasible crash and location types. For San Pablo Ave., all road segments are arterial and multi-lane. The AADT on this roadway is greater than 25,000, thererore location types 3, 5, and 6 are not useful for San Pablo Ave. The posted speed is either 35 or 40 mph, it is considered a high speed road. The road width is greater than 70 feet. The results are listed below.

Table 11. Crash Types and Crash Locations

Intersection	Crash types	Crashes with right turning vehicle
		Crashes with unsafe speed
		Crashes with pedestrian right of way in cross walk
		Crashes with pedestrian violation in cross walk
		Crashes with pedestrian violation not in cross walk
		Other than above
	Location types	Un-signalized intersection with speed limit higher than 35 mph and narrow
		Un-signalized intersection with speed limit higher than 35 mph and wide
		Un-signalized intersection with speed limit lower than 35 mph and narrow
		Un-signalized intersection with speed limit lower than 35 mph and wide
		Signalized intersection with speed limit higher than 35 mph and narrow
		Signalized intersection with speed limit higher than 35 mph and wide
		Signalized intersection with speed limit lower than 35 mph and narrow
		Signalized intersection with speed limit lower than 35 mph and wide
Road segment	Crash types	Crashes with pedestrian right of way crossing in crosswalk
		Crashes with pedestrian right of way crossing not in crosswalk
		Crashes with pedestrian violation crossing in crosswalk
		Crashes with pedestrian violation crossing not in crosswalk
		Crashes with unsafe speed crossing in crosswalk
		Crashes with unsafe speed crossing not in crosswalk
		Other than above
	Location types	Road segments with speed limit higher than 35 mph and narrow
		Road segments with speed limit higher than 35 mph and wide
		Road segments with speed limit lower than 35 mph and narrow
		Road segments with speed limit lower than 35 mph and wide

Step 2—Develop the Matrices and Input Data

As was discussed previously in the matrices section, crash and location types identified in Step 1 are used to build the "systemic hot spot identification matrix" as shown in Figure 12. Then the number of crashes corresponding to each combination of crash type and location type are calculated and inserted into the matrix. Crash numbers are highlighted in different colors from green to red, indicating the numbers from smallest to largest. In addition, a systemic hot spot matrix can be developed for road segments as shown in Figure 13.

SPA Crash Map (2005-2009)		Location type								
		1	2	3	4	5	6	7	8	
		Unsignalized; >35mph; Narrow	Unsignalized; >35mph; Wide	Unsignalized; <35mph; Narrow	Unsignalized; <35mph; Wide	Signalized; >35mph; Narrow	Signalized; >35mph; Wide	Signalized; <35mph; Narrow	Signalized; <35mph; Wide	
127 Sites		54	8	8	21	20	7	2	7	
Crash type	1 Right turning vehicle	2			1	5	3		2	13
	2 Unsafe speed		1				1			2
	3 Pedestrian right of way; In crosswalk	6		1		8	1	1	3	20
	4 Pedestrian violation; In crosswalk	1	1			3			1	6
	5 Pedestrian violation; Not In crosswalk	3	1			2	1		1	8
	6 Other	10	1		2	3	1	1		18
		22	4	1	3	21	7	2	7	67

Figure 12. Systemic Hot Spots Identification Matrix for Intersections

SPA Crash Map (2005-2009)	Location type				
	1 Unsignalized; >35mph; Narrow	2 Unsignalized; >35mph; Wide	3 Unsignalized; <35mph; Narrow	4 Unsignalized; <35mph; Wide	
30 Sites	13	5	4	8	
1 Ped right of way, crossing in crosswalk	19	4	5	3	31
2 Ped right of way, crossing not in crosswalk	1				1
3 Ped violation, crossing in crosswalk	5		2	1	8
4 Ped violation, crossing not in crosswalk	4		1	6	11
5 Unsafe speed, crossing in crosswalk		1	1		2
6 Unsafe speed, crossing not in crosswalk					0
7 Other	31	2	2	5	40
	60	7	11	15	93

(Crash type labels the rows 1–7)

Figure 13. Systemic Hot Spots Identification Matrix for Road Segments

Step 3—Identify Corresponding Safety Countermeasures for Systemic Hot Spots
Based on the data in the first matrix, the different types of collisions are distributed across various types of facilities. Each cell in the matrix relates to the corresponding safety countermeasures shown in the countermeasure matrix, Figure 14. For example, to reduce the eight collisions of crash type 3 that occurred at location type 5 (see Figure 12), the potential safety countermeasure could be either number 5, 8, or 12 which are located in the same cell as crash type 3 at location type 5 (see Figure 14). The countermeasure matrix for road segments are shown in figure 15.

SPA Crash Map (2005-2009)			Location type							
			1	2	3	4	5	6	7	8
			Unsignalized; >35mph; Narrow	Unsignalized; >35mph; Wide	Unsignalized; <35mph; Narrow	Unsignalized; <35mph; Wide	Signalized; >35mph; Narrow	Signalized; >35mph; Wide	Signalized; <35mph; Narrow	Signalized; <35mph; Wide
127 Sites			54	8	8	21	20	7	2	7
Crash type	1	Right turning vehicle	6, 7, 12	6, 7, 12	7, 12	3, 7, 12	1, 2, 6, 7, 8, 9, 10, 11	1, 2, 3, 6, 7, 8, 9, 10, 12	1, 2, 7, 8, 9, 10, 12	1, 2, 3, 7, 8, 9, 10, 12
	2	Unsafe speed	6, 12	3, 6, 11, 12	--	--	1, 2, 6, 8, 9, 10, 11	1, 2, 3, 6, 8, 9, 10, 11, 12	--	--
	3	Pedestrian right of way; In crosswalk	12	3, 11, 12	7, 12	3, 7, 11, 12	5, 8, 12	3, 5, 8, 11, 12	5, 8, 12	3, 5, 8, 11, 12

Figure 15. Countermeasure Matrix for road segments

Step 4—Select Potential Countermeasures

Based on the results from the countermeasure table, there will be several appropriate potential countermeasures from which to choose. In addition to the consideration of crash modification factors for each countermeasure, it is important to keep in mind that the systemic countermeasures will be implemented throughout all similar locations, and that certain countermeasures will have economic scale benefits if they are implemented simultaneously. A typical table as shown in Figure 16 could be developed to identify the most appropriate countermeasures installed systemically over a corridor, based on the cost and crash modification factors of the proposed countermeasures.

Countermeasure list					
#	Name	Cost	CMF_1	.	CMF_5
1	Install information signs on ped push buttons			.	
2	Install push button functioning indicator			.	
3	Install raised medians/refuge islands			.	
4	Install pedestrian crossing			.	
5	Install advance stop bar before crosswalk			.	
6	Reduce curb radius			.	
7	Imporve visibility at intersection			.	
8	Add exclusive pedestrian phasing			.	
9	Install pedestrian countdown signal heads			.	
10	Prohibit right-turn-on-red			.	
11	Install mini-circles			.	
12	Install ped overpass/underpass			.	

Figure 16. Countermeasure List for intersections

Countermeasure list					
#	Name	Cost	CMF_1	.	CMF_5
1	Implement lane reduction (Road Diet)			.	
2	Install ped overpass/underpass			.	
3	Install chokers, chicanes, speed humps, speed table			.	
4	Improve visibility			.	
5	curb extension				
6	convert 2-way to 1-way street				
7	install pedestrian warning sign or signal				
8	install pedestrain crosswalk				
9	barrier to force pedestrian cross in crosswalk				
10	stall signs for pedestrians to read				
11	install raised pedestrian crossing				

Figure 17. Countermeasure List for road segments

5 Conclusions and Recommendations

This chapter summarizes the results of this study and the recommendations.

5.1 Conclusions

A database including all VRU collisions was constructed using Statewide Integrated Traffic Records System (SWITRS) data maintained by the California Highway Patrol (CHP). The database includes all pedestrian and bicycle collisions from 1998 to 2007. Each collision was geocoded and matched to the closest intersection.

A stratification system was recommended. Different traffic modes collisions can be stratified according to their spatial related features and outcome related features, or by their environmental features such as light and weather conditions.

A systemic approach was developed for pedestrian safety along urban arterials. Applying this method, users can identify systemic hotspots which share the same high risk characteristics and specific crash types. Then the systemic countermeasures can be selected and implemented throughout all similar types of locations.

5.2 Recommendations

Data can be stratified according to the stratification method described in this report, if the characteristics are different. Pattern evaluation can test the difference between stratifications to determine whether collisions should be separated during analysis. This report offers two spatial pattern evaluations— spatial distribution and spatial consistency.

Researchers also recommend that Caltrans utilize the method proposed in this research to study pedestrian/bicycle crashes on state arterial roadways. The systemic approach is valuable for facilities that have relatively low crash frequencies and are therefore less likely to be flagged as hotspots and be considered for safety improvements. Systemic improvements typically have a lower per-site cost as they are implemented at multiple locations across a network.

Appendix 3. Data Matching of Crash Information & Countermeasures

	Crash Location		Crash Type	Countermeasures	San Pablo
Signalized	Marked Crosswalk	Indicator or not	Single vehicle involved	Install Pedestrian countdown signal heads	
Signalized	Marked Crosswalk	High ped/bike volume	Speeding	Install advanced stop bar before crosswalk	
Signalized	Unmarked crosswalk	No ped sig head, high vehicle turning movements	Ped vs turning vehicle	Install Pedestrian countdown signal heads or install crosswalk	
Signalized	Marked/ unmarked	Freeway/arterial interx, high veh. volume, high speed, rail tracks	All	Install ped overpass/underpass	Y
Signalized	Marked/ unmarked	Limited sight distance, pedestrian interaction	Ped vs right turn vehicle	Right turn on red restrictions	
Signalized	Marked/ unmarked	High ped volume	All	Pedestrian-only or pedestrian-lead phase	
Signalized	Marked/ unmarked		All	Information signs on ped push buttons	Y
Signalized	Marked/ unmarked		All	Push button functioning indicator	Y
Unsignalized	Unmarked	High vehicle volume, school zone, left/right turn pocket	All	Install crosswalk (signs and markings)	
Unsignalized	Marked/ unmarked	Long crossing distance	Speeding, light condition	Install raised medians/refuge island	Y
Unsignalized	Marked/ unmarked	High ped volume	All	Install signal with ped. Signal	
Unsignalized	Marked	High traffic volume, school zone, turns pockets	All	Install enhanced ped safety features	
Unsignalized	Marked/ unmarked	Parking lane, low vehicle speed	Multi threat	Curb extension	
Unsignalized	Marked/ unmarked	Intersections where volumes do not warrant a stop sign or a signal and intersection of	High speed intersections	Mini-circles	Y

	Crash Location		Crash Type	Countermeasures	San Pablo
		two local streets			
Sig/unsig.	Marked	Motor vehicle flows up to 1000 vehicles per hour, and with two-lane approaches	All	Advance stop lines	
Sig/unsig.	Marked/ unmarked	More night time crossing or downtown area	Light condition	Roadway lighting improvement	
Sig/unsig.	Marked/ unmarked	Bus stop on near side of intx or crosswalk	Bus related, crossing street form behind a bus	Transit stop treatment	
Sig/unsig.	Marked/ unmarked		Ped vs right turn vehicle	Improve right turn split	
Sig/unsig.	Marked/ unmarked	High conflict traffic (left turns)	Angle collisions	Roundabouts	
Sig/unsig.	Marked/ unmarked		Ped vs right turn vehicle	Curb radius reduction	
Sig/unsig.	Marked/ unmarked		High speed intersections	Intersection median barriers	
Sig/unsig.	Marked/ unmarked		High speed intersections	Raised intersections/raised median crossing	
Sig/unsig.	Marked/ unmarked	People who use wheelchairs	Ped vs right turn vehicle	Install curb ramps	
Sig/unsig.	Marked/ unmarked		Ped vs right turn vehicle	Curb radius reduction	
T-intersection	Marked/ unmarked	T-intersections on lower-volume streets in residential areas	All	Modified T-interx	
No controlled crossing for a long distance along the roadway, mid-block, and or multi-lane urban road			Crossing crashes, ped visibility	Install ped crossings ,with signs and markings, signals	
No bike lanes			Bike vs vehicle	Install bike lanes	
High speed, high vehicular traffic			Trapped/ multi-car involved	Install raised medians/refuge island	
No or not adequate sidewalks			Walking along roadway	Install sidewalk/walkway	

	Crash Location		Crash Type	Countermeasures	San Pablo
Lower speed roadways, high vehicle volume			Crossing crashes, ped visibility	Install raised pedestrian crossing	
Night ped volume, commercial area, night time crossing volume			Pedestrian visibility	Roadway lighting improvement	
Long crossing distance	Marked/ unmarked	Lower speed roadways	Multi-threat, dash/dart-out	Curb extension	
Downtown area, two way roadways			Crossing crashes	Convert two-way to one way street	
High speed, business area, one way roadway			Crossing crashes	Convert one-way to two-way street	
Bus stop on the near side of the crosswalk			Bus related	Bus stop treatment	
Long crossing distance, multi-lane urban road			Crossing crashes	Lane reduction	Y
Freeway/arterial, high vehicle volume, high speed, or rail tracks			Speeding	Install ped overpass/underpass	Y
High speed roads			Speeding	Road narrowing	Y
Commercial districts			All	Street furniture/walking environment	Y
Roadways with high number of driveways and parking			Right turning vehicles, ped visibility	Driveway improvement	
Wide roadway			Speeding	Chokers	Y
High speed, low vehicular traffic			Speeding	Chicanes, speed humps, speed table	Y
Entering a commercial, residential, or business district			Speeding	Gate ways	
Commercial, residential, or business district			Speeding	Landscaping	
Commercial, residential, or business district			Speeding	Specific paving treatment	

	Crash Location		Crash Type	Countermeasures	San Pablo
Commercial, residential, or business district			Speeding	Serpentine design	
Commercial, residential, or business district			Speeding	Woonerf	
On the roadside or on mast arms over midblock pedestrian crossings	Marked		All	Ped hybrid beacon	

Note: The data not available in TASAS are shown in gray, while available data are shown in black.
