6.2.1 INTRODUCTION

Girder bridges are structurally the simplest and the most commonly used on short to medium span bridges. Figure 6.2.1-1 shows the Central Viaduct in San Francisco. Steel I-section is the simplest and most effective solid section for resisting bending and shear. In this chapter, straight composite steel-concrete plate girder bridges are discussed. Design considerations for span and framing arrangement and section proportion are presented. A design example of the three span continuous composite plate girder bridge is given to illustrate the design procedure. For a more detailed discussion, reference may be made to texts by Chen and Duan (2014), Barker and Puckett (2013), FHWA (2015), and Taly (2014).

Figure 6.2.1-1 Central Viaduct in San Francisco

6.2.2 STRUCTURAL MATERIALS

6.2.2.1 Structural Steel

ASTM A709 or AASHTO M 270 (Grades 36, 50, 50S, 50W, HPS 50W, HPS 70W and HPS 100W) structural steels are commonly used for bridge structures. Chapter 6.1 provides a more detailed discussion. Caltrans Standard Specifications (Caltrans, 2018) 55-1.02D(3) specifies that unless otherwise described, structural steel plates, shapes, and bars must comply with ASTM A709/A709M, Grade 50. When different grades are used for the project, they shall be shown clearly on the plans.
6.2.2.2 Concrete

Concrete with 28-day compressive strength $f'_c = 3.6$ ksi is commonly used in concrete deck slab construction. Concrete deck slabs shall be designed and detailed in accordance with Structure Technical Policy (STP) 9.4 (Caltrans, 2020) and Bridge Design Memo (BDM) 9.4 (Caltrans, 2021a). The transformed area of concrete is used to calculate the composite section properties. For normal weight concrete of $f'_c = 3.6$ ksi, the ratio of the modulus of elasticity of steel to that of concrete, $n = E/E_c = 8$, is recommended by AASHTO (2017).

For unshored construction, the modular ratio $n$ is used for transient loads applied to the short-term composite sections, and the modular ratio $3n$ is used for permanent loads applied to the long-term composite sections (Article 6.10.1.1.1.b).

6.2.3 SPAN AND FRAMING ARRANGEMENT

6.2.3.1 Span Configuration

Span configuration plays an important role in the efficient and cost-effective use of steel. For cases where pier locations are flexible, designers should optimize the span arrangement. Two-span continuous girders/beams are not the most efficient system because of high negative moments. Three- and four-span continuous girders are preferable but may not always be possible. For multi-span continuous girders, a good span arrangement is to have the end span lengths approximately 70 to 80 percent of the interior span lengths. Equal interior span arrangements are also relatively economical. A span configuration with uplift due to live load plus impact should be avoided.

The use of simply supported girders under construction load and continuous girders through steel reinforcement for the live load can be an economical framing method (Azizinamini, 2007). This type of framing presents possible advantages over continuous beam designs by eliminating costly splices and heavy lifts during girder erection. The potential drawbacks are that more section depth may be required, and the weight of steel per unit deck area may be higher. This framing method needs to be investigated on a case-by-case basis to determine whether it can be economically advantageous. This simple span for the dead load and continuous for the live load steel bridge system has gained popularity in low-hazard seismic regions. Its application in seismic regions is being studied (Taghinezhadbilondy, 2016), and seismic details have yet to be developed and codified.

When simply supported span configurations are used, special attention should be given to seismic performance detailing.

In a horizontally curved alignment, two types of girder layout systems, horizontally curved girders or continuous kinked (chorded) straight girders, are used. Horizontally curved girders are slightly simpler in girder layout and analysis and are generally understood to be more aesthetically pleasing than continuous kinked girders. The curved girders are
usually more time consuming to fabricate and erect, but their constant deck overhang can expedite the construction process. The kinked straight girders are faster to fabricate and erect, but their variable deck overhangs are less efficient to construct (Lewis, 2016). By placing kinks within low demand regions, the overall kinked girder system can be optimized, and the reduction of the primary tension member of cross frames that require Charpy V-notch testing is significant. For a small horizontal curve, the cost of required kinks to accommodate deck overhang or cross frame forces may be higher than the cost savings of fabrication and erection. Therefore, the girder system should be carefully selected by considering its unique sets of advantages and disadvantages to having a cost effective solution.

6.2.3.2 Girder Spacing

As a general rule, the most economical superstructure design can be achieved using girder spacing within the 10 ft to 14 ft range. For spans less than 140 ft, 10 ft to 12 ft spacing is preferred. For spans greater than 140 ft, 11 ft to 14 ft spacing is recommended. The use of stay-in-place metal form panels will limit the spacing to about 16 ft. Girder spacings over 16 ft may require a transversely post-tensioned deck system. A parallel girder layout should be used wherever possible.

6.2.3.3 Diaphragms and Cross Frames

The terms diaphragm and cross frame are synonymous. Figure 6.2.3-1 shows typical types of diaphragms and cross frames used in I-shaped plate girder and rolled beam spans. The K-frames and X-frames usually include a top strut, as shown in Figure 6.2.3-1. Intermediate cross frames provide bracing against lateral torsional buckling of compression flanges during erection and deck concrete placement, and for all loading stages in negative flexure regions. They also provide lateral bracing for wind loads. End cross frames or diaphragms at piers and abutments are provided to transmit lateral wind loads and seismic loads to the bearings.

6.2.3.3.1 Spacing

An arbitrary 25 ft spacing limit for diaphragms and cross frames was specified in the AASHTO Standard Specifications for Highway Bridges (AASHTO, 2002) and the Caltrans Bridge Design Specifications (Caltrans, 2000). The AASHTO LRFD Bridge Design Specifications (AASHTO, 2017) no longer specify a limit on the cross frame spacing, but instead require rational analysis to investigate needs for all stages of assumed construction procedures and the final conditions. Spacing should be compatible with the transverse stiffeners.
6.2.3.3.2 Spacing Orientation

Intermediate cross frames shall be placed parallel to the skew up to a 20° skew and normal to the girders for a skew angle larger than 20° (Article 6.7.4.2). On skewed bridges with cross frames placed normal to the girders, there may be situations where the cross frames are staggered or discontinuous across the width of the bridge. At these discontinuous cross frames, lateral flange bending stresses may be introduced into the girder flanges and should be considered. Install stiffeners on the back side of connection plates if staggered cross frames are used. Horizontally curved girders should always have cross frames placed on radial lines.

A good economical design will minimize the number of diaphragms with varying geometries. Superelevation changes, vertical curves, different connection plate widths, and flaring girders all work against this goal.

6.2.3.3.3 Connections

Cross frames are typically connected to transverse stiffeners. The stiffeners shall have a positive connection to the girder flange and may either be bolted or welded, although welding is preferred.
For bridges built in stages or with larger skew angles, differential deflections between girders due to slab placement can be significant. If differential deflections are significant, slotted holes and hand tight erection bolts with jam nuts shall be provided during concrete placement, and permanent bolts fully tensioned, or field welded connections shall be installed after the barriers are placed. The bolt holes can be field drilled to ensure proper fit. Intermediate cross frames between stages shall be eliminated if possible.

6.2.3.3.4 Design Guidelines

- The diaphragm or cross frame shall be as deep as practicable to transfer lateral load and to provide lateral stability. They shall be at least 0.5 of the beam depth for rolled beams and 0.75 of the girder depth for plate girders (AASHTO 6.7.4.2).

- Cross frames should be designed and detailed such that they can be erected as a single unit, and all welding during fabrication should be done from one side to minimize handling costs. As a minimum, cross frames shall be designed to resist lateral wind loads. A rational analysis is preferred to determine actual lateral forces.

- End diaphragms and cross frames at bearings shall be designed to resist all lateral forces transmitted to the substructure. Unless they are detailed as ductile elements, the end diaphragms or cross frames shall be designed to resist the overstrength shear capacity of the substructures. Shear connectors should be provided to transfer lateral loads from the deck to the end diaphragm in accordance with the Caltrans Seismic Design Specifications for Steel Bridges (Caltrans, 2016). When an expansion joint occurs at the support, the end diaphragm shall be designed to resist truck wheel and impact loads.

- Effective slenderness ratios \((Kl/r)\) for compression diagonal braces shall be less than or equal to 120 for primary members in horizontally curved girders and 140 for secondary members in straight girders, respectively (Article 6.9.3).

- Slenderness ratio \((l/r)\) for tension diagonal braces shall be less than or equal to 200 for primary members in horizontally curved girders and 240 for secondary members in straight girders, respectively (Article 6.8.4).

- Cross frame members and gussets consisting of single angle or WT shapes should be designed for the eccentricity inherent at the gusset connections. Use rectangular gusset plates instead of multi-sided polygons.

- Steel plate, I girder, and concrete diaphragms may be used at abutments and piers. The use of integral abutments, piers, and bents is encouraged.

6.2.3.3.5 Proposed New Design Specifications

For the design of cross frames, Article 6.7.4 (AASHTO, 2017) requires rational analysis to investigate the needs for all stages of assumed construction procedures and the final conditions. However, no detailed provisions are provided. NCHRP Project 12-113 (Reichenbach et al., 2021) “Proposed Modification to AASHTO Cross-Frame Analysis and Design,” will be adopted in the future AASHTO LRFD Bridge Design Specifications.
6.2.3.4 Lateral Bracing

Bottom chord lateral bracing should be avoided because the bracing creates fatigue-sensitive details and is costly to fabricate, install, and maintain. Flange sizes should be sufficient to preclude the need for bottom flange lateral bracing.

6.2.3.5 Field Splice Locations

Field splices should preferably be located at points of the dead load contraflexure and points of section change. It is usually spaced more than 50 ft. apart. The splice locations are also dependent on shipping and fabrication limits. The length of a shipping piece is usually less than 125 ft. and the weight is less than 180 kip. It is not necessary to locate the splices at the exact contraflexure point, but they should be reasonably close. Field splices are sometimes required to be placed near points of the maximum moment in longer spans to meet erection requirements. Field splices should be bolted. Welded field splices should be avoided if possible. Adjacent girders should be spliced in approximately the same location.

6.2.3.6 Expansion Joints and Hinges

In-span hinges are generally not recommended for steel bridges since there are not many acceptable solutions for the design of hinges to resist seismic loads. Steel bridges have been designed without expansion joints and hinges at lengths up to 1200 ft. When dropped cap bents are utilized, the superstructure may be separated from the substructure with expansion bearings to prevent undue temperature effects on the substructure.

6.2.4 SECTION PROPORTION

6.2.4.1 Depth to Span Ratios

Figure 6.2.4-1 shows a typical portion of a composite I-girder bridge consisting of a concrete deck and built-up plate girder I-section with stiffeners and cross frames. The first step in the structural design of a plate girder bridge is to initially size the web and flanges.
For straight girders, AASHTO Table 2.5.2.6.3-1 specifies the minimum ratio of the depth of steel girder portion to the span length is 0.033 for simply supported spans and 0.027 for continuous spans. The minimum ratio of the overall depth (concrete slab plus steel girder) to span length is 0.04 for simply supported spans and 0.032 for continuous spans. Caltrans traditionally prefers that the minimum ratio of overall depth to span length is 0.045 for simply supported spans and 0.04 for continuous spans, primary for live load deflection control. For horizontally curved girders, the minimum depth will more than likely need to be increased by 10 to 20%.

6.2.4.2 Webs

The web mainly provides shear strength for the girder. Since the web contributes little to the bending resistance, its thickness should be as small as practical to meet the web depth to thickness ratio limits $D/t_w \leq 150$ for webs without longitudinal stiffeners and $D/t_w \leq 300$ for webs with longitudinal stiffeners, respectively (Article 6.10.2.1). It is preferable to have web depths in increments of 2 or 3 in. for convenience. Web depths greater than 120 in. will require both longitudinal and vertical splices.

The web thickness is preferred to be not less than $\frac{1}{2}$ inch. A thinner plate is subject to excessive distortion from welding. The thickness should be sufficient to preclude the need for longitudinal stiffeners. Web thickness should be constant or with a limited number of changes. A reasonable target would be one or two web sizes for a continuous girder and one web size for a simple span. Web thickness increments should be 1/16 in. or 1/8 in. for the plate thicknesses up to 1 inch and $\frac{1}{4}$ inch increments for plates greater than 1 inch.

6.2.4.3 Flanges

The flanges provide bending strength. Flanges should be at least 12 in. wide. A constant
flange width for the entire length of the girder is preferred. If the flange area needs to be increased, it is preferable to change the flange thickness. If flange widths need to be changed, it is best to change the width at field splices only. Width increments should be in multiples of 2 or 3 inches. For horizontally curved girders, the flange width should be about one-fourth of the web depth. For straight girders, a flange width of approximately one-fifth to one-sixth of the web depth should be sufficient.

For straight girders, the minimum flange thickness should be 3/4 inches. For curved girders, 1 in. thickness is a practical minimum. The desirable maximum flange thickness is 3 inches. Grade 50 and HPS 70W steels are not available in thicknesses greater than 4 inches. Flange thickness increments should be 1/8 in. for thicknesses up to 1 in., 1/4 in. from 1 to 3 in., and 1/2 in. from 3 to 4 inches. At the locations where the flange thickness is changed, the thicker flange should provide about 25 percent more area than the thinner flange. In addition, the thicker flange should be not greater than twice the thickness of the thinner flange.

Both the compression and tension flanges shall meet the following proportion requirements (Article 6.10.2.2) as follows:

\[
\frac{b_f}{2t_f} \leq 12 \quad \text{(AASHTO 6.10.2.2-1)}
\]

\[
b_f \geq \frac{D}{6} \quad \text{(AASHTO 6.10.2.2-2)}
\]

\[
t_f \geq 1.1t_w \quad \text{(AASHTO 6.10.2.2-3)}
\]

\[
0.1 \leq \frac{I_{yc}}{I_{yt}} \leq 10 \quad \text{(AASHTO 6.10.2.2-4)}
\]

where

- \(b_f\) = full width of the flange (in.);
- \(t_f\) = thickness of the flange (in.)
- \(I_{yc}\) = moment of inertia of the compression flange about the vertical axis in the plane of the web, (in.\(^4\))
- \(I_{yt}\) = moment of inertia of the tension flange about the vertical axis in the plane of the web (in.\(^4\))
- \(D\) = web depth (in.)

AASHTO Eq. 6.10.2.2-1 ensures the flange will not distort excessively when welded to the web. AASHTO Eq. 6.10.2.2-2 ensures that stiffened interior web panels can develop post-elastic buckling shear resistance by the tension field action. AASHTO Eq. 6.10.2.2-3 ensures that flanges can provide some restraint and proper boundary conditions to resist web shear buckling. AASHTO Eq. 6.10.2.2-4 ensures more efficient flange proportions and prevents the use of sections that may be difficult to handle during construction. It also ensures that the lateral torsional buckling formulas used in AASHTO
6.2.4.4 Stiffeners

Intermediate transverse stiffeners together with the web are used to provide post-elastic shear buckling resistance by the tension field action and are usually placed near the supports and large concentrated loads. Stiffeners without connecting cross frames/diaphragms are typically welded to the girder web and shall be welded to the compression flange and fitted tightly to the tension flange (CA 6.10.11.1.1). Stiffener plates are preferred to have even inch widths from the flat bar stock sizes. To give a clean and pleasing appearance to the bridge, it is normal to have intermediate transverse stiffeners, at points rather than bearings on the interior face of the exterior girder.

Bearing stiffeners are required at all bearing locations. Bearing stiffeners shall be welded or bolted to both sides of the web. Bearing stiffeners should be thick enough to preclude the need for multiple pairs of bearing stiffeners to avoid multiple-stiffener fabrication difficulties. Article 6.10.11.2 requires that the stiffeners shall extend the full depth of the web and as close as practical to the edge of the flanges.

Longitudinal stiffeners are required to increase flexure resistance of the web by controlling lateral web deflection and preventing from the web bending buckling. They are, therefore, attached to the compression portion of the web. It is recommended that sufficient web thickness be used to eliminate the need for longitudinal stiffeners as they can cause difficulty in fabrication and create fatigue-prone details.

6.2.5 STRUCTURAL MODELING AND ANALYSIS

Steel girder bridges are commonly modeled as beam elements and analyzed as unshored construction. The flexural stiffness of the composite section is assumed over the entire bridge length, even though the negative moment regions may be designed as non-composite for the section capacity. Longitudinal reinforcing steel in the top mat of the concrete deck within the effective deck width is generally not included in calculating section properties.

In the preliminary analysis, a constant flexural stiffness may be assumed. In the final analysis of composite flexural members, the stiffness properties of the steel section alone for the loads applied to noncomposite sections, the stiffness properties of the long-term composite section for permanent loads applied to composite sections, and the stiffness properties of the short-term composite section properties for transient loads shall be used over the entire bridge length (Article 6.10.1.5).

Dead loads are usually distributed to the girders based on the tributary area. Live loads distribution is dependent on the girder spacing \( S \), the span length \( L \), the concrete slab depth \( t_s \), the longitudinal stiffness parameter \( K_{G} \), and the number of girders \( N_b \) (Article 4.6.2.2.1).

The refined analysis using the finite element method may be used in analyzing complex bridge systems such as skewed and horizontally curved bridges.
6.2.6 DESIGN LIMIT STATES AND PROCEDURES

6.2.6.1 Design Limit States

Steel girder bridges shall be designed to meet the requirements for all applicable limit states specified by AASHTO (2017) and the California Amendments (Caltrans 2019a), such as Strength I, Strength II, Service II, Fatigue I and II, and extreme events. Constructability (Article 6.10.3) must be considered. See Chapters 3, 4, and 6.1 for a more detailed discussion.
6.2.6.2 Design Procedure

The steel girder design may follow the flowchart as shown in Figure 6.2.6-1.

Start

Select girder layout, framing system, and sections

Perform load and structural analysis

Determine LRFD load combinations (CA Table 3.4.1-1)

Perform Flexure Design for the Limit States - Strength (AASHTO 6.10.6.2), Service (AASHTO 6.10.4), Fatigue (AASHTO 6.10.5.1), and Constructibility (AASHTO 6.10.3.2)

Perform Shear Design for the Limit States - Strength (AASHTO 6.10.6.3), Fatigue (AASHTO 6.10.5.1), and Constructibility (AASHTO 6.10.3.3)

Perform Shear Connector Design (AASHTO 6.10.10)

Perform Bearing Stiffener Design (AASHTO 6.10.11.2)

Perform Cross Frame Design

Perform Bolted Field Splices Design (AASHTO and CA 6.13.6)

Calculate Deflection and Camber

Girder Design Completed

Figure 6.2.6-1 Steel I-Girder Design Flowchart
6.2.7 DESIGN EXAMPLE – THREE-SPAN CONTINUOUS COMPOSITE PLATE GIRDER BRIDGE

6.2.7.1 Steel Girder Bridge Data

A three-span continuous composite plate girder bridge located in an urban area has spans of 110 ft – 165 ft – 125 ft. The superstructure is 58 ft wide. The elevation and plan are shown in Figure 6.2.7-1.

Structural steel: A709 Grade 50 for web, flanges and splice plates $F_y = 50$ ksi

A709 Grade 36 for cross frames and stiffeners, etc. $F_y = 36$ ksi

Concrete: $f'_c = 3600$ psi; modular ratio $n = 8$

Deck: Concrete deck slab thickness = 9.125 in.

Construction: Unshored construction

Figure 6.2.7-1 Three-span Continuous Steel Plate Girder Bridge
6.2.7.2 Design Requirements

Perform the following design portions for an interior plate girder in accordance with the AASHTO LRFD Bridge Design Specifications, 8th Edition (AASHTO, 2017) with the California Amendments (Caltrans, 2019a).

- Select Girder Layout and Sections
- Perform Load and Structural Analysis
- Calculate Live Load Distribution Factors
- Determine Load and Resistance Factors and Load Combinations
- Calculate Factored Moments and Shears – Strength Limit States
- Calculate Factored Moments and Shears – Fatigue Limit States
- Calculate Factored Moments – Service Limit State II
- Design Composite Section in Positive Moment Region at 0.5 Point of Span 2
- Design Noncomposite Section in Negative Moment Region at Bent 3
- Design Shear Connectors for Span 2
- Design Bearing Stiffeners at Bent 3
- Design Intermediate Cross Frames
- Design Bolted Field Splices
- Calculate Camber and Plot Camber Diagram
- Identify and Designate Steel Bridge Members and Components

6.2.7.3 Select Girder Layout and Sections

6.2.7.3.1 Select Girder Spacing

A girder spacing of 12 ft is selected as shown in Figure 6.2.7-2a.

6.2.7.3.2 Select Intermediate Cross Frame Spacing

Cross frames at spacing of 27.5 ft and 25 ft are selected as shown in Figure 6.2.7-3 to accommodate transverse stiffener spacing for web design and to facilitate a reduction in the required flange thickness of the girder section at the bent.
Figure 6.2.7-2 Typical Cross Sections

(a) Bridge Cross Section

(b) Interior Girder Section
For convenience in this example, the ends of the girder have been assumed to match the BB and EB locations.

**Figure 6.2.7-4 Elevation of Interior Girder**

### 6.2.7.3.3 Select Steel Girder Section for Positive Flexure Regions

The cross section is usually proportioned based on past practice and proportion limits specified in Article 6.10.2. The interior girder section is shown in Figures 6.2.7-2b and 6.2.7-4. Haunch depth should be carefully selected by considering road slope, top flange thickness, correction of sagging and cambers, and embedment of shear connectors as discussed in Bridge Design Details (BDD) 11.4 (Caltrans, 2019b).
Top Compression Flange

The maximum transported length of a steel plate girder is generally limited to a length of about 125 ft and a weight of about 180 kips and may vary due to the locations. It is common practice that the unsupported length of each shipping piece divided by the minimum width of compression flange should be less than or equal to about 85 (Article C6.10.3.4.1). For a length of 120 ft, the width of the compression flange is preferably larger than \((120 \times 12)/85 = 17\) in.

Try top compression flange \(b_{fc} \times t_{fc} = 18 \times 1\) (in. \(\times\) in.).

Web

AASHTO Table 2.5.2.6.3-1 specifies that for composite girders, the minimum ratio of the depth of steel girder portion to the length of the span is 0.033 for simple spans and 0.027 for continuous spans. For this design example, the depth of the steel girder shall be larger than 0.027(165) = 4.46 ft. = 53.5 in.

Try web \(D \times tw = 78 \times 0.625\) (in. \(\times\) in.).

Bottom Tension Flange

Try bottom tension flange \(b_{ft} \times t_{ft} = 18 \times 1.75\) (in. \(\times\) in.).

Check Section Proportion Limits

- Web without longitudinal stiffeners

\[
\frac{D}{t_w} = \frac{78}{0.625} = 124.8 < 150 \quad \text{O.K.} \quad \text{(AASHTO 6.10.2.1.1-1)}
\]

- Compression flange

\[
\frac{b_{fc}}{2t_{fc}} = \frac{18}{2(1.0)} = 9 < 12 \quad \text{O.K.} \quad \text{(AASHTO 6.10.2.2-1)}
\]

\[
b_{fc} = 18 \text{ in.} \quad > \frac{D}{6} = \frac{78}{6} = 13 \text{ in.} \quad \text{O.K.} \quad \text{(AASHTO 6.10.2.2-2)}
\]

\[
t_{fc} = 1.0 \text{ in.} \quad > 1.1t_w = 1.1(0.625) = 0.69 \text{ in.} \quad \text{OK.} \quad \text{(AASHTO 6.10.2.2-3)}
\]

- Tension flange

\[
\frac{b_{ft}}{2t_{ft}} = \frac{18}{2(1.75)} = 5.14 < 12 \quad \text{O.K.} \quad \text{(AASHTO 6.10.2.2-1)}
\]
\[ b_f = 18 \text{ in.} > \frac{D}{6} = \frac{78}{6} = 13 \text{ in.} \quad \text{O.K.} \quad \text{(AASHTO 6.10.2.2-2)} \]

\[ t_f = 1.75 \text{ in.} > 1.1t_w = 1.1(0.625) = 0.69 \text{ in.} \quad \text{O.K.} \quad \text{(AASHTO 6.10.2.2-3)} \]

- **Flanges Ratio**

The flange shall meet the requirement of \[0.1 \leq \frac{I_{yc}}{I_{yt}} \leq 10,\] where \(I_{yc}\) and \(I_{yt}\) are the moment of inertia of the compression flange and the tension flange about the vertical axis in the plane of the web, respectively. This limit ensures more efficient flange proportions and prevents the use of sections that may be difficult to handle during construction. It also ensures that the lateral torsional buckling formulas are valid.

\[ 0.1 < \frac{I_{yc}}{I_{yt}} = \frac{(1)(18)^3 / 12}{(1.75)(18)^3 / 12} = 0.57 < 10 \quad \text{O.K} \quad \text{(AASHTO 6.10.2.2-4)} \]

### 6.2.7.3.4 Select Steel Girder Section for Negative Flexure Regions

**Flanges**

In the negative moment region, a non-composite symmetric steel section is generally used.

Try flange plate \(b_f \times t_f = 18 \times 2 \text{ (in. \times in.)}\).

**Web**

It is more cost effective to use one thickness plate for the web through the whole bridge.

Try web \(D \times t_w = 78 \times 0.625 \text{ (in. \times in.)}\).

**Check Section Proportion Limits**

- Web without longitudinal stiffeners:

\[ \frac{D}{t_w} = \frac{78}{0.625} = 124.8 < 150 \quad \text{O.K.} \quad \text{(AASHTO 6.10.2.1.1-1)} \]

- Compression and tension flanges

\[ \frac{b_f}{2t_f} = \frac{18}{2(2.0)} = 4.5 < 12 \quad \text{O.K.} \quad \text{(AASHTO 6.10.2.2-1)} \]

\[ b_f = 18 \text{ in.} > \frac{D}{6} = \frac{78}{6} = 13 \text{ in.} \quad \text{O.K.} \quad \text{(AASHTO 6.10.2.2-2)} \]

6.2-20  Chapter 6.2 Steel Plate Girders

\[ t_r = 2.0 \text{ in.} > 1.1t_w = 1.1(0.625) = 0.69 \text{ in.} \quad \text{O.K. (AASHTO 6.10.2.2-3)} \]

- Flange ratio

\[
0.1 \leq \frac{l_{yc}}{l_{yt}} = \frac{(2)(18)^3}{12} / \frac{(2)(18)^3}{12} = 1.0 < 10 \quad \text{O.K. (AASHTO 6.10.2.2-4)}
\]

6.2.7.3.5 Select Transverse Stiffeners

It is normal to use stiffener width of 7.5 in. to provide allowances for gusset plate connections of cross frames.

Try a pair of stiffeners \( b_t \times t_p = 7.5 \times 0.5 \) (in. \( \times \) in.)

6.2.7.3.6 Select Bolted Splice Locations

For flexural members, splices shall preferably be made at or near points of dead load contraflexure in continuous spans and at points of the section change. As shown in Figure 6.2.7-3, splice locations for Spans 1 and 3 are selected approximately at the 0.7 and the 0.3 points, respectively, and for Span 2 are selected approximately at the 0.3 and the 0.7 points.

6.2.7.4 Perform Load and Structural Analysis

6.2.7.4.1 Calculate Permanent Loads for an Interior Girder

The permanent load or dead load of an interior girder includes \( DC \) and \( DW \). \( DC \) is dead load of structural components and nonstructural attachments. \( DW \) is dead load of wearing surface. For design purposes, the two parts of \( DC \) are defined as, \( DC_1 \), structural dead load, acting on the non-composite section, and \( DC_2 \), nonstructural dead load, acting on the long-term composite section.

\( DC_1 \) usually consists of deck slab concrete (unit weight 150 lbs/ft\(^3\)), and steel girders including bracing systems and details (estimated weight 460 lbs/ft for each girder). California Amendment (CA) Article 3.5.1 (Caltrans, 2019a) specifies that dead load, \( DC \), of cast-in-place concrete decks between precast concrete and steel girder flange edges shall be increased by 10 percent to compensate for the use of permanent steel deck forms. An approximate top flange thickness of 1.5 in. and \( DC_1 \) are assumed to be distributed to each girder by the tributary area. The tributary width for the interior girder is 12 feet.

\[
DC_1 = \left[(1.1)(9.125/12)(12-1.5) + (1.5)(13.25-1.5)/12\right] (0.15) + 0.46 = 2.0 \text{ kip/ft}
\]

\( DC_2 \) usually consists of the barrier rails and specified utility. Type 842 Concrete Barriers
(0.64 kip/ft and bottom width = 1.75 ft) are used and no utility is considered for this bridge. DC2 is assumed to be distributed equally to each girder.

\[ DC2 = \left(\frac{2 \times 0.64}{5}\right) = 0.256 \text{ kip/ft} \]

\[ DW = \left(\frac{\text{deck width} - \text{barrier width} \times \text{wearing surface weight}}{5}\right) \]

\[ = \left[\frac{58 - 2 \times 1.75}{5}\right] \times 0.035 = 0.382 \text{ kip/ft} \]

**6.2.7.4.2 Determine Live Load and Dynamic Load Allowance**

The design live load LL is the AASHTO HL-93 (ARTICLE 3.6.1.2) and Caltrans P15 vehicular live loads (CA 3.6.1.8). To consider the wheel-load impact from moving vehicles, the dynamic load allowance \( IM = 33\% \) for the Strength I limit state, 25\% for the Strength II limit state, and 15\% for the Fatigue limit states are used (CA Table 3.6.2.1-1).

**6.2.7.4.3 Perform Structural Analysis**

Structural analysis for three-span continuous beams shall be performed to obtain moments and shear effects due to dead loads and live loads, including impact. In the preliminary analysis, a constant flexural stiffness may be assumed. In the final analysis of composite flexural members, the stiffness properties of the steel section alone for the loads applied to noncomposite sections, the stiffness properties of the long-term composite section for permanent loads applied to composite sections, and the stiffness properties of the short-term composite section properties for transient loads shall be used over the entire bridge length (Article 6.10.1.5). In this design example, the analysis is performed by the CT-Bridge computer program and checked by the CSiBridge program. A constant flexural stiffness is assumed for simplicity.

Unfactored dead load for an interior girder and live load moments, shears, and support forces for one lane loaded are listed in Tables 6.2.7-1, 6.2.7-2, and 6.2.7-3, respectively. Unfactored moment and shear envelopes for one lane loaded in Span 2 are plotted in Figures 6.2.7-5 and 6.2.7-6, respectively.

Figure 6.2.7-6 Unfactored Shear Envelopes for Span 2
6.2.7.5 Calculate Live Load Distribution Factors

6.2.7.5.1 Check Ranges of Applicability of Live Load Distribution Factors

For beam-slab bridges, the distribution of live load is dependent on the girder spacing \( S \), span length \( L \), the concrete slab depth \( t_s \), the longitudinal stiffness parameter \( K_g \), and the number of girders \( N_b \). This example is categorized as Type “a” (AASHTO Table 4.6.2.2.1-1).

The preliminary section shown in Table 6.2.7-4 is assumed to estimate the longitudinal stiffness parameter, \( K_g \) (AASHTO 4.6.2.2.1-1), for the positive moment region in Span 2.

Table 6.2.7-4 Preliminary Section Properties for Positive Moment Region

<table>
<thead>
<tr>

<td>75,146</td>
<td>24,726</td>
</tr>
</tbody>
</table>

\[
y_{NCI} = (1.75 + 78 + 1) - 35.2 = 45.55 \text{ in.}
\]

\[
y_{NCB} = \frac{\sum A_i y_i}{\sum A_i} = \frac{3,458.7}{98.25} = 35.2 \text{ in.}
\]

\[
l_{NC} = \sum l_o + \sum A_i (y_i - y_{NCB})^2
= 24,726 + 75,146 = 99,872 \text{ in.}^4
\]

\[
e_g = 45.55 - 1.0 + 13.25 - \frac{9.125}{2} = 53.24 \text{ in.}
\]

\[
K_g = n \left( l_{NC} + A e_g^2 \right) = 8 \left[ 99,872 + (98.25)(53.24)^2 \right] = 3,026,891 \text{ in.}^4
\]

Check ranges of applicability of AASHTO Tables 4.6.2.2.2b-1 and 4.6.2.2.3a-1 for Type “a” structure.

Girder spacing: \( 3.5 \text{ ft} < S = 12 \text{ ft} < 16 \text{ ft} \)

Span length: \( 20 \text{ ft} < L = (110, 165 \text{ and } 125) \text{ ft} < 240 \text{ ft} \)
Concrete deck: 4.5 in. < $t_s$ = 9.125 in. < 12.0 in.

Number of girders: $N_b = 5 > 4$

Stiffness parameter: $10,000 \text{ in.}^4 < K_g = 3,026,891 \text{ in.}^4 < 7,000,000 \text{ in.}^4$

It is seen that the girder satisfies the limitation of ranges of applicability of the approximate live load distribution factors specified in AASHTO Tables 4.6.2.2.2b-1 and 4.6.2.2.3a-1. Section type “a” (AASHTO Table 4.6.2.1-1) will be used.

Although the $K_g$ term varies slightly along the span and between spans, the distribution factor is typically not sensitive to the value of $K_g$. For simplicity, the $K_g$ of Span 2 is used for all spans of this example.

### 6.2.7.5.2 Determine Span Length for Use in Live Load Distribution Equations

AASHTO Table 4.6.2.2.1-2 recommends the $L$ for use in live load distribution equations, as shown in Table 6.2.7-5.

<table>
<thead>
<tr>
<th>Force Effects</th>
<th>$L$ (ft)</th>

</tbody>
</table>

### 6.2.7.5.3 Calculate Live Load Distribution Factors

Live load distribution factors are calculated and listed in Tables 6.2.7-6 and 6.2.7-7 in accordance with AASHTO Tables 4.6.2.2.2b-1 and 4.6.2.2.3a-1.

One design lane loaded

$$DF_m = 0.06 + \left( \frac{S}{14} \right)^{0.4} \left( \frac{S}{L} \right)^{0.3} \left( \frac{K_g}{12Lt_s^3} \right)^{0.1}; \quad DF_v = 0.36 + \frac{S}{25}$$

Two or more design lanes loaded

$$DF_m = 0.075 + \left( \frac{S}{9.5} \right)^{0.6} \left( \frac{S}{L} \right)^{0.2} \left( \frac{K_g}{12Lt_s^3} \right)^{0.1}; \quad DF_v = 0.2 + \frac{S}{12} - \left( \frac{S}{35} \right)^2$$
\[ K_g = 3,026,891 \text{ in.}^4 \]
\[ S = 12 \text{ ft} \]
\[ t_s = 9.125 \text{ in.} \]

### Table 6.2.7-6 Live Load Distribution Factors for Interior Girder for Strength Limit State

<table>
<thead>
<tr>
<th>Span</th>
<th>Lane loaded</th>
<th>Moment ( DF_m ) (Lane)</th>
<th>Shear ( DF_v ) (Lane)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>

<td>0.834</td>
</tr>
<tr>
<td>3*</td>
<td>L = 125 ft</td>
<td>0.573</td>
<td>0.869</td>
</tr>
</tbody>
</table>

**Note:**
- * The span length for which moment is being calculated for positive moment, negative moment—other than near interior supports of continuous spans, shear, and exterior reaction.
- ** Average span length for the negative moment—near interior supports of continuous spans from point of contraflexure to point of contraflexure under a uniform load on all spans, and interior reaction of continuous spans.

Multiple lane presence factors have been included in the above live load distribution factors.

It is seen that live load distribution factors for the case of two or more lanes loaded control the strength and service limit states. For the fatigue limit states, since live load is one HL-93 truck or one P9 truck as specified CA 3.6.1.4.1, a multiple lane presence factor of 1.2 should be removed from the above factors for the case of one lane loaded (AASHTO 3.6.1.1.2).
Table 6.2.7-7 Live Load Distribution Factors for Interior Girder

</tbody>
</table>

Note:
* The span length for which moment is being calculated for positive moment, negative moment—other than near interior supports of continuous spans, shear, and exterior reaction.
** Average span length for negative moment—near interior supports of continuous spans from point of contraflexure to point of contraflexure under a uniform load on all spans, and interior reaction of continuous spans.

6.2.7.6 Determine Load and Resistance Factors and Load Combinations

A steel girder bridge is usually designed for the Strength limit state and checked for the Fatigue limit state, Service limit state II, and Constructability.

6.2.7.6.1 Determine Design Equation

Article 1.3.2.1 requires that the following design equation shall be satisfied for all limit states:

$$
\sum \eta_i \gamma_i Q_i \leq \phi R_n = R_r
$$

(AASHTO 1.3.2.1-1)

where $\gamma_i$ is load factor and $\phi$ is resistance factor; $Q_i$ represents force effect; $R_n$ is nominal resistance; $\eta_i$ is load modifier factor related to ductility, redundancy, and operational importance and is defined as follows when a maximum value of $\gamma_i$ is used:

$$
\eta_i = \eta_D \eta_R \eta_I \geq 0.95
$$

(AASHTO 1.3.2.1-2)

where $\eta_D$, $\eta_R$, and $\eta_I$ are ductility and redundancy and operational factors, respectively. CA 1.3.3, 1.3.4 and 1.3.5 specify that they are all taken to 1.0 for all limit states. Therefore, $\eta_i = 1.0$. For this example, the design equation becomes:

$$
\sum \gamma_i Q_i \leq \phi R_n = R_r
$$

(6.2.7.2.6-1)
6.2.7.6.2  Determine Applicable Load Factors and Load Combinations

According to CA Table 3.4.1-1, considering live load distribution factors for the interior girder and denoting \((LL+IM)\) as unfactored force effect due to one design lane loaded, the following load combinations are obtained as:

Strength I: \(1.25(\text{DC}) + 1.5(\text{DW}) + 1.75(\text{DF})(LL+IM)_{\text{HL-93}}\)
Strength II: \(1.25(\text{DC}) + 1.5(\text{DW}) + 1.35(\text{DF})(LL+IM)_{\text{P15}}\)
Service II: \(1.0(\text{DC}) + 1.0(\text{DW}) + 1.30(\text{DF})(LL+IM)_{\text{HL-93}}\)
Fatigue I: \(1.75(\text{DF})(LL+IM)_{\text{HL-93}}\)
Fatigue II: \(1.0(\text{DF})(LL+IM)_{\text{P9}}\)

where \(\text{DF}\) is the live load distribution factor.

6.2.7.6.3  Determine Applicable Resistance Factors

According to Article 6.5.4.2, the following resistance factors are used for the strength limit states in this example.

For flexure \(\phi_f = 1.00\)
For shear \(\phi_v = 1.00\)
For axial compression \(\phi_c = 0.90\)
For tension, fracture in net section \(\phi_u = 0.80\)
For tension, yielding in gross section \(\phi_y = 0.95\)
For bearing on milled surfaces \(\phi_b = 1.00\)
For bolts bearing on material \(\phi_{bb} = 0.80\)
For shear connector \(\phi_{sc} = 0.85\)
For block shear \(\phi_{bs} = 0.80\)
For ASTM F3125 bolts in shear \(\phi_s = 0.80\)
For weld metal in fillet weld
  – shear in throat of weld metal \(\phi_{e2} = 0.80\)

6.2.7.7  Calculate Factored Moments and Shears – Strength Limit States

Using live load distribution factors in Table 6.2.7-6, factored moments, shears, and support forces for strength limit states I and II are calculated and listed in Tables 6.2.7-8, 6.2.7-9, and 6.2.7-10, respectively.

Chapter 6.2 Steel Plate Girders
### 6.2.7.8 Calculate Factored Moments and Shears – Fatigue Limit States

For load-induced fatigue consideration (CA Table 3.4.1-1), the fatigue moment and shear force ranges are caused by live load only and are calculated by the following equations:

<table>
<thead>
<tr>
<th>Fatigue I (HL-93 Truck)</th>
<th>( \gamma(\Delta F) = 1.75 \left( DF_{LL+IM}\right)_{HL-93} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fatigue II (P-9 Truck)</td>
<td>( \gamma(\Delta F) = 1.0 \left( DF_{LL+IM}\right)_{P9} )</td>
</tr>
</tbody>
</table>

Using live load distribution factors in Table 6.2.7-7, fatigue limit moment and shear ranges for an interior girder are calculated and listed in Tables 6.2.7-11 and 6.2.7-12. \( V_u \), shear due to the unfactored dead load plus the factored fatigue load (Fatigue I) is also calculated for checking the special fatigue requirement for webs as required by AASHTO 6.10.5.3.

\[
V_u = V_{DC1} + V_{DC2} + V_{DW} + (1.75)\left( DF_{i} \right)(LL + IM)_{HL-93}
\]

6.2.7.10 Design Composite Section in Positive Moment Region at 0.5 Point of Span 2

For midspan sections, design is normally governed by bending moments. In the following, only the flexural design for the 0.5 Point Section is illustrated. A similar shear design procedure is shown in Section 6.2.7.11.

6.2.7.10.1 Illustrate Calculations of Factored Moments – Strength Limit States

Factored force effects are calculated and summarized in Section 6.2.7.7. Table 6.2.7-14 illustrates detailed calculations for factored moments at the 0.5 Point of Span 2.

**Strength II:** $1.25(DC) + 1.5(DW) + 1.35(DF)(LL+IM)_{P15}$

6.2.7.10.2 Calculate Elastic Section Properties

**Determine Effective Flange Width**

According to Articles 4.6.2.6.1 and C4.6.2.6.1, the effective flange width may be taken as the tributary width perpendicular to the axis of the member when the girder span to the spacing ratio ($L/S$) is larger than 3.1. In this design example, $S = 12$ ft and $L = 165$ ft. For the interior girder in Span 2, the effective flange width is as:
\[ L / S = 165 / 12 = 13.75 > 3.1 \]
\[ b_{\text{eff}} = b = 12 \text{ ft} = 144 \text{ in.} \]  
\[ \text{(AASHTO 4.6.2.6.1)} \]

**Calculate Elastic Section Properties**

Elastic section properties for the steel section alone, the steel section and deck slab longitudinal reinforcement, the short-term composite section \((n = 8)\), and the long-term composite section \((3n = 24)\) are calculated and shown in Tables 6.2.7-15 to 6.2.7-18.

### Table 6.2.7-15 Properties of Steel Section Alone

\[
y_{NCb} = \frac{\sum A_i y_i}{\sum A_i} = \frac{3,458.7}{98.25} = 35.2 \text{ in.} \\
y_{NCl} = (1.75 + 78 + 1) - 35.2 = 45.55 \text{ in.} \\
I_{NC} = \sum I_o + \sum A_i (y_i - y_{NCb})^2 \\
= 24,726 + 75,146 = 99,872 \text{ in.}^4 \\
S_{NCb} = \frac{I_{NC}}{y_{NCb}} = \frac{99,872}{35.2} = 2,837 \text{ in.}^3 \\
S_{NCl} = \frac{I_{NC}}{y_{NCl}} = \frac{99,872}{45.55} = 2,193 \text{ in.}^3 
\]
Properties of the steel section alone may be conservatively used for calculating stresses under negative moments. In this example, properties of the steel section and deck slab longitudinal reinforcement are used for calculating stresses due to negative moments (AASHTO 6.10.1.1.1c). Assume the total area of longitudinal reinforcement in the deck slab is 1% of the concrete deck slab area; we have $A_s$:

$$A_s = 0.01(12 \times 12)(9.125) = 13.14 \text{ in.}^2$$

\]

\[
y_{LTb} = (1.75 + 78 + 1) - 54.25 = 26.5 \text{ in.}
\]

\[
I_{LT} = \sum I_o + \sum A_i (y_i - y_{LTb})^2 + 100,252 + 99,655 = 199,907 \text{ in.}^4
\]

\[
S_{LTb} = \frac{I_{LT}}{y_{LTb}} = \frac{199,907}{54.25} = 3,685 \text{ in.}^3
\]

\[
S_{LT} = \frac{I_{LT}}{y_{LTb}} = \frac{199,907}{26.5} = 7,544 \text{ in.}^3
\]

It should be pointed out that the concrete haunch is ignored in calculating composite section properties.
6.2.7.10.3 Design for Flexure – Strength Limit State

**General Requirement**

At the strength limit state, the composite compact section in positive moment regions shall satisfy the requirement as follows:

\[ M_u + \frac{1}{3} f_i S_{xt} \leq \phi M_n \]  

(AASHTO 6.10.7.1.1-1)

In this example of the straight bridge, flange lateral bending stress for interior girders \( f_i = 0 \). The design equation, therefore, is simplified as follows:

\[ M_u \leq \phi M_n \]

(6.2.7.10.3-1)

**Check Section Compactness**

For composite sections in the positive moment region, it is usually assumed that the top flange is adequately braced by the hardened concrete deck. There is no requirement for the compression flange slenderness and bracing for compact composite sections at the strength limit state. Three requirements (Article 6.10.6.2.2) for a compact composite section in straight bridges are checked as follows:

Specified minimum yield strength of flanges:

\[ F_{yf} = 50 \text{ ksi} < 70 \text{ ksi} \]

O.K.  

(AASHTO 6.10.6.2.2)

Web:

\[ \frac{D}{t_w} = 124.8 < 150 \]

O.K.  

(AASHTO 6.10.2.1.1-1)

Section:

\[ \frac{2D_{cp}}{t_w} \leq \frac{3.76 E}{F_{yc}} \]

(AASHTO 6.10.6.2.2-1)

where \( D_{cp} \) is the depth of the web in compression at the plastic moment state and is determined in the following.

Compressive force in the concrete slab:

\[ P_s = 0.85 t_s' b_{eff} t_s = 0.85(3.6)(144)(9.125) = 4,021 \text{ kip} \]

in which \( t_s \) is the thickness of the concrete slab

Yield force in the top compression flange:
\[ P_c = A_{wc}F_{yc} = (18 \times 1)(50) = 900 \text{ kip} \]

Yield force in the web:
\[ P_w = A_{w}F_{yw} = (78 \times 0.625)(50) = 2,438 \text{ kip} \]

Yield force in the bottom tension flange:
\[ P_t = A_{ht}F_{yt} = (18 \times 1.75)(50) = 1,575 \text{ kip} \]

\[ \therefore P_s + P_c = 4,021 + 900 = 4,921 \text{ kip} > P_w + P_t = 2,438 + 1,575 = 4,013 \text{ kip} \]

\[ \therefore \text{The plastic neutral axis is within the top compression flange (AASHTO Table D6.1-1), and } D_{cp} \text{ is equal to zero.} \]

\[ \frac{2D_{cp}}{t_w} = 0.0 < 3.76 \sqrt{\frac{E}{F_{yc}}} \quad \text{O.K. (AASHTO 6.10.6.2.2-1)} \]

When the plastic neutral axis is within the web, \( D_{cp} \) can be calculated in accordance with AASHTO Tables D6.1-1 or D6.1-2.

The section meets the requirements for the composite compact section in positive flexure. The nominal flexural resistance, \( M_n \), is, therefore, calculated in accordance with Article 6.10.7.1.2 (AASHTO, 2017; Caltrans, 2019a).

**Calculate Plastic Moment \( M_p \)**

At the plastic moment state, the compressive stress in the concrete slab of a composite section is assumed equal to \( 0.85f'_c \), and tensile stress in the concrete slab is neglected. The stress in the reinforcement and the steel girder section is assumed equal to \( F_y \). The reinforcement in the concrete slab is neglected in this example. The plastic moment \( M_p \) is determined using equilibrium equations and is the first moment of all forces about the plastic neutral axis (Article D6.1).

- **Determine Location of Plastic Neutral Axis (PNA)**

  As calculated above, the plastic neutral axis (PNA) is within the top flange of the steel girder. Denote that \( \overline{y} \) is the distance from the top of the compression flange to the PNA as shown in Figure 6.2.7-7, we obtain:

  \[ P_s + P_{c1} = P_{c2} + P_w + P_t \]

  where

  \[ P_{c1} = \overline{y} b_{lc}F_{yc} \]
\[ P_{c2} = (t_{fc} - \bar{y}) b_{fc} F_{yc} \]

In which \( b_{fc} \) and \( t_{fc} \) are the width and the thickness of the top flange of the steel section, respectively; \( F_{yc} \) is the yield strength of the top compression flange of the steel section.

Substituting the above expressions into the equilibrium equation for \( \bar{y} \) obtain

\[ \bar{y} = \frac{t_{fc}}{2} \left( \frac{P_w + P_t - P_s}{P_c} + 1 \right) \]

\[ \bar{y} = \frac{1}{2} \left( \frac{2,438 + 1,575 - 4,021}{900} + 1 \right) = 0.496 \text{ in.} < t_{fc} = 1.0 \text{ in.} \text{ O.K.} \]

![Figure 6.2.7-7 Plastic Moment Capacity State](image)

**Figure 6.2.7-7 Plastic Moment Capacity State**

- **Calculate Plastic Moment \( M_p \)**
  
  Summing all forces about the PNA, obtain:

\[
M_p = \sum M_{PNA} = P_s d_s + P_{c1} \left( \frac{\bar{y}}{2} \right) + P_{c2} \left( \frac{t_{cf} - \bar{y}}{2} \right) + P_w d_w + P_t d_t
\]

\[
= P_s d_s + b_{fc} F_{yc} \left( \frac{(\bar{y})^2 + (t_{cf} - \bar{y})^2}{2} \right) + P_w d_w + P_t d_t
\]

where

\[
d_s = \frac{9.125}{2} + 4.125 - 1 + 0.496 = 8.18 \text{ in.}
\]
\[ d_w = \frac{78}{2} + 1 - 0.496 = 39.50 \text{ in.} \]
\[ d_t = \frac{1.75}{2} + 78 + 1 - 0.496 = 79.38 \text{ in.} \]

\[ M_p = (4,021)(8.18) + (18)(50)\left(\frac{0.496^2 + (1-0.496)^2}{2}\right) + (2,438)(39.5) + (1,575)(79.38) \]
\[ = 254,441 \text{ kip-in.} = 21,203 \text{ kip-ft} \]

**Calculate Yield Moment \( M_y \)**

The yield moment \( M_y \) corresponds to the first yielding of either steel flange. It is obtained by the following formula (AASHTO D6.2):

\[ M_y = M_{D1} + M_{D2} + M_{AD} \]

(AASHTO D6.2.2-2)

From Section 6.2.7.10.1, factored moments, \( M_{D1} \) and \( M_{D2} \) are as follows:

\[ M_{D1} = M_{DC1} = 3,269 \text{ kip-ft} \]
\[ M_{D2} = M_{DC2} + M_{DW} = 420 + 765 = 1,185 \text{ kip-ft} \]

Using section moduli \( S_{NC} \), \( S_{ST} \), and \( S_{LT} \) as shown in Section 6.2.7.10.2 for the non-composite steel, the short-term and the long-term composite section, we have:

\[ M_{AD} = S_{ST} \left( F_y - \frac{M_{D1}}{S_{NC}} - \frac{M_{D2}}{S_{LT}} \right) \]

For the top flange:

\[ M_{AD} = (22,489) \left( 50 - \frac{3,269(12)}{2,193} - \frac{1,185(12)}{7,544} \right) \]
\[ = 679,780 \text{ kip-in.} = 56,565 \text{ kip-ft} \]

For the bottom flange:

\[ M_{AD} = (4,018) \left( 50 - \frac{3,269(12)}{2,837} - \frac{1,185(12)}{3,685} \right) \]
\[ = 129,837 \text{ kip-in.} = 10,820 \text{ kip-ft} \]
\[
\therefore M_y = 3,269 + 1,185 + 10,820 = 15,274 \text{ kip-ft}
\]

**Calculate Flexural Resistance**

In this example, it is assumed that the adjacent interior-bent sections are non-compact non-composite sections that do not satisfy the requirements of AASHTO B6.2. The nominal flexural resistance of the composite compact section in positive flexure is calculated in accordance with AASHTO and CA 6.10.7.1.2:

\[
M_n = \min \left\{ M_p, \left[ M_p \left[ 1 \left( 1 - \frac{M_y}{M_p} \right) \left( \frac{D_p}{D_t} - 0.1 \right) \right] \right] \right\}
\]

for \( D_p \leq 0.1D_t \)

\[
M_n = \min \left\{ M_p, \left[ M_p \left( 1 - \frac{M_y}{M_p} \right) \left( \frac{D_p}{D_t} - 0.1 \right) \right] \right\}
\]

for \( D_p > 0.1D_t \)

(AASHTO and CA 6.10.7.1.2-1,2)

For a continuous span:

\[
M_n \leq 1.3 R_h M_y
\]

(AASHTO 6.10.7.1.2-3)

where \( R_h \) is a hybrid factor (AASHTO 6.10.1.10.1) and is equal to 1.0 for this example; \( D_p \) is the depth from the top of the concrete deck to the PNA; \( D_t \) is the total depth of the composite section.

The compact and noncompact sections shall satisfy the following ductility requirement to ensure that the tension flange of the steel section reaches significant yielding before the crushing strain is reached at the top of the concrete deck.

\[
D_p \leq 0.42D_t
\]

(AASHTO 6.10.7.3-1)

\[
D_p = 13.25 - 1 + 0.496 = 12.75 \text{ in.}
\]

\[
D_t = 1.75 + 78 + 13.25 = 93 \text{ in.}
\]

\[
D_p = 12.75 \text{ in.} < 0.42D_t = 0.42(93) = 39.06 \text{ in.} \quad \text{O.K.}
\]

\[
D_p = 12.75 \text{ in.} > 0.1D_t = 9.3 \text{ in.}
\]

\[
M_n = \left[ 1 - \left( 1 - \frac{M_y}{M_p} \right) \left( \frac{D_p}{D_t} - 0.1 \right) \right] M_p
\]

\[
= \left[ 1 - \left( 1 - \frac{15,274}{21,203} \left( \frac{12.75}{93} - 0.1 \right) \right) \right] (21,203) = 20,516 \text{ kip-ft}
\]

\[
> 1.3R_h M_y = (1.3)(1.0)(15,274) = 19,856 \text{ kip-ft}
\]

Use \( M_n = 19,856 \text{ kip-ft} \)
Check Design Requirement

\[ M_u = 11,949 \text{ kip-ft} < \phi M_n = (1.0)(19,856) = 19,856 \text{ kip-ft} \quad \text{O.K. (6.2.7.10.3-1)} \]

6.2.7.10.4 Illustrate Calculations of Fatigue Moment Ranges

Fatigue moment ranges are calculated and summarized in Section 6.2.7.8. For the 0.5 Point of Span 2, using the live load distribution factor \( DF_m = 0.433 \) (Table 6.2.7.7), fatigue moment ranges are as follows:

Fatigue I:

\[
M = \gamma(DF_m)(LL + IM)_{HL} = (1.75)(0.433)(LL + IM)_{HL-93} \\
+M = (1.75)(0.433)(1,715) = 1,299 \text{ kip-ft} \\
M = (1.75)(0.433)(-302) = -229 \text{ kip-ft}
\]

Fatigue II:

\[
M = \gamma(DF_m)(LL + IM)_{P9} = (1.0)(0.433)(LL + IM)_{P9} \\
+M = (1.0)(0.433)(5,144) = 2,227 \text{ kip-ft} \\
-M = (1.0)(0.433)(-933) = -404 \text{ kip-ft}
\]

6.2.7.10.5 Check Typical Girder Details – Fatigue Limit States

For load-induced fatigue consideration, the most common types of details in a typical plate girder are (AASHTO Table 6.6.1.2.3-1) listed in Table 6.1.8-1, and nominal fatigue resistances for those typical details are shown in Table 6.1.8-2 in Chapter 6.1.

For a section in the positive moment region within mid-span, such as the section at the 0.5 Point of Span 2, flexural behavior usually dominates the design. Positive live load moments are applied to the short-term composite section, and negative live load moments are applied to the steel section and deck slab longitudinal reinforcement (AASHTO 6.10.1.1.1c). Fatigue stress ranges at the bottom flanges, and the top flanges are checked as follows:

**Fatigue I - HL-93 Truck for Infinite Life:**

Flexural fatigue stress ranges at the bottom flange:

\[
\gamma(\Delta f) = \frac{+M}{S_{STb}} + \frac{-M}{S_{Ncb}} = \frac{1,299(12)}{4,018} + \frac{229(12)}{3,200} \\
= 3.88 + 0.86 = 4.74 \text{ ksi} < 12.0 \text{ ksi} \quad \text{O.K. for Category C’} \\
< 16.0 \text{ ksi} \quad \text{O.K. for Category B}
\]
Flexural fatigue stress ranges at the top flange:

\[
\gamma(\Delta f) = \frac{+M}{S_{STI}} + \frac{-M}{S_{NCT}} = \frac{1,299(12)}{22,489} + \frac{229(12)}{3,380}
\]

\[
< 10.0 \text{ ksi} \quad \text{O.K. for Category C}
\]

\[
= 0.69 + 0.81 = 1.50 \text{ ksi} < 12.0 \text{ ksi} \quad \text{O.K. for Category C'}
\]

\[
< 16.0 \text{ ksi} \quad \text{O.K. for Category B}
\]

**Fatigue II - P-9 Truck for Finite Life:**

Flexural fatigue stress ranges at the bottom flange:

\[
\gamma(\Delta f) = \frac{+M}{S_{STb}} + \frac{-M}{S_{NCb}} = \frac{2,227(12)}{4,018} + \frac{404(12)}{3,200}
\]

\[
= 6.65 + 1.52 = 8.17 \text{ ksi} < 21.58 \text{ ksi} \quad \text{O.K. for Category C'}
\]

\[
< 30.15 \text{ ksi} \quad \text{O.K. for Category B}
\]

Flexural fatigue stress ranges at the top flange:

\[
\gamma(\Delta f) = \frac{+M}{S_{STI}} + \frac{-M}{S_{NCT}} = \frac{2,227(12)}{22,489} + \frac{404(12)}{3,380}
\]

\[
< 21.58 \text{ ksi} \quad \text{O.K. for Category C}
\]

\[
= 1.19 + 1.43 = 2.62 \text{ ksi} < 21.58 \text{ ksi} \quad \text{O.K. for Category C'}
\]

\[
< 30.15 \text{ ksi} \quad \text{O.K. for Category B}
\]

**6.2.7.10.6 Check Requirements - Service II Limit State**

**General Requirements**

Service II limit state is to control the elastic, and permanent deflections under the design live load HL-93 (AASHTO 6.10.4). The live load deflection \( \Delta \) may not exceed \( L/800 \) (AASHTO 2.5.2.6.2) and is calculated and checked in Section 6.2.7.16.

**Illustrate Calculations of Factored Moments - Service II Limit State**

It is noted that for unshored construction, \( DC1, DC2+DW \), and live load are applied to the non-composite (steel section alone), long-term, and short-term composite sections, respectively. Factored moments at the Service II limit state are calculated and summarized in Table 6.2.7-13. The calculations of factored moments for the 0.5 Point of Span 2 are illustrated as follows:

\[
M_{DC1} = 2,615 \text{ kip-ft} \quad \text{(applied to steel section alone)}
\]
Check Flange Stresses

In this example, $f_t = 0$ for this interior girder. The requirement becomes:

$$f_t = \frac{M_{DC1}}{S_{NC}} + \frac{M_{DC2} + M_{DW}}{S_{LT}} + \frac{M_{(LL+IM)HL-93}}{S_{ST}} \leq 0.95R_hF_{yt}$$

$$= 0.95(1.0)(50) = 47.5 \text{ ksi}$$

For the top flange of the composite section

$$f_t = \frac{(2615)(12)}{2193} + \frac{(846)(12)}{7544} + \frac{(3616)(12)}{22489} \leq 47.5 \text{ ksi}$$

O.K. (AASHTO 6.10.4.2.2-1)

$$= 14.31 + 1.35 + 1.93 = 17.59 \text{ ksi} < 47.5 \text{ ksi}$$

For the bottom flange of the composite section

$$f_t = \frac{(2615)(12)}{2837} + \frac{(846)(12)}{3685} + \frac{(3616)(12)}{4018} \leq 47.5 \text{ ksi}$$

O.K. (AASHTO 6.10.4.2.2-2)

$$= 11.06 + 3.08 + 10.80 = 24.94 \text{ ksi} < 47.5 \text{ ksi}$$

Article 6.10.4.2.2 states that except for composite sections in positive flexure in which the web satisfies the requirement of Article 6.10.2.1.1, i.e., $D/t_w < 150$, all sections shall also satisfy the AASHTO Eq. 6.10.4.2.2-4. In this example,

$$\frac{D}{t_w} = \frac{78}{0.625} = 124.8 < 150$$

(AASHTO 6.10.2.1.1-1)

∴ The compression flange check of AASHTO Eq. 6.10.4.2.2-4 is not required.

Check Concrete Deck Stresses

Article 6.10.4.2.2 specifies that for compact composite sections in positive flexure utilized in shored construction, the longitudinal compressive stress in the concrete deck due to the Service II loads shall not exceed $0.6f'_c$. Since unshored construction is assumed in this example, there is no need to check compressive stress in the concrete deck.
6.2.7.10.7 Check Requirements - Constructability

General Requirements

At construction stages, steel girders of Span 2 with an unbraced compression flange length \( L_b = 330 \text{ in.} \) carry out the construction load, including dead load (self-weight of steel girders and concrete deck slab) and other loads acting on the structure during construction. To prevent nominal yielding or reliance on post-buckling resistance of the steel girder during critical stages of construction, the following Article 6.10.3 requirements for flexural stresses are checked. For the 0.5 Point Section, shear effects are very small, and the shear strength check is not illustrated. A similar design procedure is shown in Section 6.2.7.11.

Calculate Factored Moment – Constructability

In the constructability check, all loads shall be factored as specified in Article 3.4.2. In this example, no other construction load is assumed, and only factored dead loads are applied on the noncomposite section. The compression flange is discretely braced with an unbraced length \( L_b = 330 \text{ in.} \) within Span 2. The factored moment at the 0.5 Point of Span 2 is:

\[
M_u = M_{DC1} = 1.25(2,615) = 3,269 \text{ kip-ft}
\]

Check Compression Flange

- Web Compactness

  Limiting slenderness ratio for a noncompact web:

  \[
  \lambda_{rw} = 5.7 \sqrt{\frac{E}{F_{yc}}} = 5.7 \sqrt{\frac{29,000}{50}} = 137.3 \quad \text{(AASHTO 6.10.1.10.2-4)}
  \]

  \[
  D_c = y_{NCl} - t_{fc} = 45.55 - 1.0 = 44.55 \text{ in.} \quad \text{(See Table 6.2.7-15)}
  \]

  \[
  \therefore \quad \frac{2D_c}{t_w} = \frac{2(44.55)}{(0.625)} = 142.6 > \lambda_{rw} = 137.3
  \]

  The web is slender, and AASHTO Equations 6.10.3.2.1-2 and 6.10.3.2.1-3 shall be checked.

- Calculate Flange-Strength Reduction Factors \( R_h \) and \( R_b \)

  Since homogenous plate girder sections are used for this example, hybrid factor \( R_h \) is taken as 1.0 (AASHTO 6.10.1.10.1).

  When checking constructability according to AASHTO 6.10.3.2, the web load-
shedding factor, \( R_b \), is taken as 1.0 (AASHTO 6.10.1.10.2).

- **Calculate Flexural Resistance**

The nominal flexural resistance of the compression flange is the smaller of the local buckling resistance (AASHTO 6.10.8.2.2) and the lateral torsional buckling resistance (AASHTO 6.10.8.2.3)

**Local buckling resistance**

\[ \lambda_f = \frac{b_{fc}}{2t_{fc}} = \frac{18}{2(1)} = 9 \quad < \quad \lambda_{pf} = 0.38 \sqrt[6]{E} = 0.38 \sqrt[6]{\frac{29,000}{50}} = 9.15 \]

\[ F_{nc(FLB)} = R_b R_n F_{yc} = (1.0)(1.0)(50) = 50 \text{ ksi} \quad \text{(AASHTO 6.10.8.2.2-1)} \]

**Lateral torsional buckling resistance**

\[ r_t = \sqrt{\frac{b_{fc}}{12 + \frac{1}{3} b_{fc} t_{fc}}} = \sqrt{\frac{18}{12 + \frac{1}{3} (18)(1.0)}} = 4.22 \text{ in.} \quad \text{(AASHTO 6.10.8.2.3-9)} \]

\[ L_p = 1.0 r_t \sqrt{\frac{E}{F_{yc}}} = (1.0)(4.22) \sqrt{\frac{29,000}{50}} = 101.6 \text{ in.} \]

\[ F_{yr} = \text{smaller} \left\{ \begin{array}{c} 0.7F_{yc} = (0.7)(50) \\ F_{yw} = 50 \end{array} \right\} = 35 \text{ksi} > 0.5F_{yc} = 25 \text{ ksi} \]

Use \( F_{yr} = 35 \text{ ksi} \)

\[ L_r = \pi r_t \sqrt{\frac{E}{F_{yr}}} = (\pi)(4.22) \sqrt{\frac{29,000}{35}} = 381.6 \text{ in.} \quad \text{(AASHTO 6.10.8.2.3-5)} \]

\[ \therefore \quad L_p = 101.6 \text{ in.} \quad L_b = 330 \text{ in.} \quad L_r = 381.6 \text{ in.} \]
\[
F_{nc(LTB)} = C_b \left[ 1 - \left( 1 - \frac{F_{yr}}{R_y F_{yc}} \right) \left( \frac{L_b - L_p}{L_r - L_p} \right) \right] R_b R_y F_{yc}
\]
\[
= (1.0) \left[ 1 - \left( 1 - \frac{35}{(1.0)(50)} \right) \left( \frac{330 - 101.6}{381.6 - 101.6} \right) \right] (1.0)(1.0)(50)
\]
\[
= 37.8 \text{ ksi} < R_b R_y F_{yc} = (1.0)(1.0)(50) = 50 \text{ ksi}
\]
(AASHTO 6.10.8.2.3-2)

Use \(F_{nc(LTB)} = 37.8\) ksi

It should be pointed out that \(C_b\) factor is taken as 1.0 conservatively for the 0.5 Point of Span 2. The nominal flexural resistance of the compression flange is:

\[
F_{nc} = \min \left( F_{nc(FLB)}, F_{nc(LTB)} \right) = \min (50, 37.8) = 37.8 \text{ ksi}
\]

\[
f_{bu} = \frac{M_u}{S_{NCt}} = \frac{3,269(12)}{2,193} = 17.9 \text{ ksi} \quad \text{O.K.} \quad \text{(AASHTO 6.10.3.2.1-2)}
\]

\[
f_{bu} < \phi_f F_{nc} = 37.8 \text{ ksi}
\]

**Calculate Web Bend-buckling Resistance**

\[
k = 9 \left( \frac{D}{D_c} \right)^2 = 9 \left( \frac{78}{44.55} \right)^2 = 27.59
\]

\[
F_{crw} = \frac{0.9 E k}{D^2_{tw}} = \frac{0.9(29,000)(27.59)}{78^2} = 46.2 \text{ ksi}
\]

(AAASHTO 6.10.1.9.1-1)

\[
< \text{smaller} \quad \begin{cases} R_y F_{yc} = (1.0)(50) = 50 \text{ ksi} \\ F_{yw} / 0.7 = 50 / 0.7 = 71.4 \text{ksi} \end{cases}
\]

Use \(F_{crw} = 46.2\) ksi

\[
f_{bu} = 17.9 \text{ ksi} < \phi_f F_{crw} = 46.2 \text{ ksi} \quad \text{O.K.} \quad \text{(AASHTO 6.10.3.2.1-3)}
\]

**Check Tension Flange**

\[
f_{bu} = \frac{M_u}{S_{NCb}} = \frac{3,269(12)}{2,837} = 13.8 \text{ ksi} < \phi_f R_y F_{yt} = 50 \text{ ksi}
\]

O.K. \quad \text{(AASHTO 6.10.3.2.2-1)}
6.2.7.11 Design Noncomposite Section in Negative Moment Region at Bent 3

In this example, steel girder sections in negative moment regions are designed as noncomposite sections. When shear connectors are provided in negative moment regions according to Article 6.10.10, sections are considered as composite sections.

6.2.7.11.1 Illustrate Calculations of Factored Moments and Shears – Strength Limit States

Factored moments and shears are calculated and summarized in Section 6.2.7.7. Tables 6.2.7-19 and 6.2.7-20 illustrate detailed calculations for the section at Bent 3.

Table 6.2.7-19 Factored Moments at Section of Bent 3

### 6.2.7.11.2 Calculate Elastic Section Properties

In order to calculate the stresses, deflection, and camber for this continuous composite girder, the elastic section properties for the steel section alone, the steel section and the deck slab longitudinal reinforcement, the short-term composite section, and the long-term composite section are calculated in Tables 6.2.7-21, 6.2.7-22, 6.2.7-23, and 6.2.7-24, respectively.

### Table 6.2.7-21 Properties of Steel Section Alone

<table>
<thead>
<tr>
<th>Component</th>

<td>-</td>
<td>4,950.75</td>
<td>-</td>
<td>115,200</td>
<td>24,740</td>
</tr>
</tbody>
</table>

\[
y_{NCb} = \frac{\sum A_i y_i}{\sum A_i} = \frac{4,950.75}{120.75} = 41.0 \text{ in.}
\]

\[
y_{NCf} = (2 + 78 + 2) - 41.0 = 41.0 \text{ in.}
\]

\[
l_{NC} = \sum I_o + \sum A_i (y_i - y_{NCb})^2 = 24,740 + 115,200 = 139,940 \text{ in.}^4
\]

\[
S_{NCb} = \frac{l_{NC}}{y_{NCb}} = \frac{139,940}{41.0} = 3,413 \text{ in.}^3
\]

\[
S_{NCf} = \frac{l_{NC}}{y_{NCf}} = \frac{139,940}{41.0} = 3,413 \text{ in.}^3
\]

Assuming the total area of longitudinal reinforcement is 1% of the concrete area at the interior supports, $A_s = 0.01(12 \times 12)(9.125) = 13.14 \text{ in.}^2$, elastic section properties of the
steel section and deck slab longitudinal reinforcement are calculated in Table 6.2.7-22 as follows.

### Table 6.2.7-22 Properties of Steel Section and Deck Slab Reinforcement

<table>
<thead>

</tr>
</tbody>
</table>

\[ y_{LTb} = \frac{\sum A_i y_i}{\sum A_i} = \frac{9,806.6}{175.5} = 55.88 \text{ in.} \]

\[ y_{LTl} = (2 + 78 + 2) - 55.88 = 26.12 \text{ in.} \]

\[ I_{ST} = \sum I_o + \sum A_i (y_i - y_{LTb})^2 \]

\[ = 140,320 + 85,674 = 225,994 \text{ in}^4 \]

\[ S_{LTb} = \frac{I_{LT}}{y_{LTb}} = \frac{225,994}{55.88} = 4,044 \text{ in}^3 \]

\[ S_{LTl} = \frac{I_{LT}}{y_{LTl}} = \frac{225,994}{26.12} = 8,652 \text{ in}^3 \]

It should be pointed out that the concrete haunch is ignored in calculating composite section properties.

### 6.2.7.11.3 Design for Flexure - Strength Limit States

#### General Requirements

For composite I-sections in negative flexure and non-composite I-sections with compact or non-compact webs in straight bridges, it is strongly recommended to use provisions in AASHTO Appendix A6. In this example of the straight bridge, flange lateral bending stress for interior girders $f_i = 0$. The design equations, therefore, are simplified as follows:

\[ M_u \leq \phi_f M_{nc} \quad (6.2.7.11.3-1) \]

\[ M_u \leq \phi_f M_{nl} \quad (6.2.7.11.3-2) \]

#### Check Section Compactness

Three requirements for noncompact sections are checked as follows:

Specified minimum yield strength of the flanges and web:

\[ F_y \leq 70 \text{ ksi} \quad (\text{AASHTO A6.1}) \]

Web:
\[
\frac{2D_c}{t_w} = \frac{78}{0.625} = 124.8 < \lambda_{rw} = 5.7 \sqrt{\frac{E}{F_{yc}}} = 5.7 \sqrt{\frac{29,000}{50}} = 137.3 \ (\text{AASHTO A6.1-1})
\]

Flange ratio:
\[
\frac{l_{yc}}{l_{yt}} = \frac{(2)(18)^3 / 12}{(2)(18)^3 / 12} = 1.0 > 0.3 \ (\text{AASHTO A6.1-2})
\]

Since the section at Bent 3 is noncompact, the nominal flexural resistance of the I-section is calculated in accordance with AASHTO Appendix A6. It is the smaller of the local buckling resistance (AASHTO A6.3.2) and the lateral torsional buckling resistance (AASHTO A6.3.3).

**Calculate Flange-Strength Reduction Factors \( R_h \) and \( R_b \)**

Since homogenous plate girder sections are used for this example, hybrid factor \( R_h \) is taken as 1.0 (AASHTO 6.10.1.10.1). As shown above, the web is noncompact, and web load-shedding factor \( R_b \) is taken as 1.0 (AASHTO 6.10.1.10.2).

**Calculate Flexural Resistance – Based on Compression Flange**

The nominal flexural resistance based on the compression flange is smaller of the local buckling resistance (AASHTO A6.3.2) and the lateral torsional buckling resistance (AASHTO A6.3.3).

- **Calculate Local Buckling Resistance**

  \[
  \lambda_f = \frac{b_{fc}}{2t_{fc}} = \frac{18}{2(2)} = 4.5 < \lambda_{pf} = 0.38 \sqrt{\frac{E}{F_{yc}}} = 0.38 \sqrt{\frac{29,000}{50}} = 9.15
  \]

  \[
  M_{nc(FLB)} = R_{pc} M_{yc} \quad \text{(AASHTO A6.3.2-1)}
  \]

  \[
  M_p = 2 \left[ (18 \times 2)(50)(40) + (39 \times 0.625)(50)(19.5) \right] = 191,531 \text{ kip-in.} = 15,961 \text{ kip-ft}
  \]

  \[
  M_{yc} = S_x F_{yt} = (3,413)(50) = 170,650 \text{ kip-in.} = 14,221 \text{ kip-ft}
  \]

  \[
  D_{cp} = D_c = 39 \text{ in.} \quad \text{(Section is symmetric about the neutral axis)}
  \]

  \[
  \lambda_{rw} = 5.7 \sqrt{\frac{E}{F_{yc}}} = 5.7 \sqrt{\frac{29,000}{50}} = 137.3
  \]
\[
\lambda_{pw(Dcp)} = \frac{29,000}{\sqrt{50\left(0.54 - \frac{15,961}{(1.0)(14,221)} \right) - 0.09}} = 90.43 < \lambda_{rw} \left(\frac{D_{cp}}{D_c}\right) = 137.3
\]

\[
\therefore \frac{2D_{cp}}{t_w} = \frac{(2)(39)}{0.625} = 124.8 > \lambda_{pw(Dcp)} = 90.43 \quad \text{(AASHTO A6.2.1-1)}
\]

and \( \lambda_w = 124.8 < \lambda_{rw} = 137.3 \) \quad \text{(AASHTO A6.2.2-1)}

Therefore, for a symmetric section in this example, the web is non-compact, and the web plastification factor is calculated as follows:

\[
\lambda_{pw(Dc)} = \lambda_{pw(Dcp)} \left(\frac{D_c}{D_{cp}}\right) = 90.43 < \lambda_{rw} = 137.3 \quad \text{(AASHTO A6.2.2-6)}
\]

\[
R_{pc} = \left[ 1 - \left( 1 - \frac{R_p M_{yc}}{M_p} \left( \frac{\lambda_w - \lambda_{pw(Dc)}}{\lambda_{rw} - \lambda_{pw(Dc)}} \right) \right) \right] \frac{M_p}{M_{yc}}
\]

\[
= \left[ 1 - \left( 1 - \frac{1.0}{15,961} \left( \frac{124.8 - 90.43}{137.3 - 90.43} \right) \right) \right] \frac{15,961}{14,221} = 1.033 \quad \text{(AASHTO A6.2.2-4)}
\]

\[
M_{nc(FLB)} = R_{pc} M_{yc} = (1.033)(14,221) = 14,690 \text{ kip-ft} \quad \text{(AASHTO A6.3.2-1)}
\]

• **Calculate Lateral Torsional Buckling Resistance**

In negative moment regions, the bottom compression flange is braced by the cross frame with a spacing of \( L_b = 330 \text{ in.} \) at Span 2 side.

\[
h = \text{depth between centerline of flanges} = (1.0 + 78 + 1.0) = 80 \text{ in.}
\]

\[
r_t = \frac{b_{fc}}{\sqrt{12 \left(1 + \frac{1 D_c t_w}{3 b_{fc} t_{fc}}\right)}} = \frac{18}{\sqrt{12 \left(1 + \frac{1(39)(0.625)}{3(18)(2.0)}\right)}} = 4.7 \text{ in.}
\]

\[
L_p = 1.0 r_t \sqrt{\frac{E}{F_{yc}}} = (1.0)(4.7) \sqrt{\frac{29,000}{50}} = 113.2 \text{ in.}
\]

Ignoring rebar, from Table 6.2.7-21 we have \( S_{xc} = S_{xt} = S_{NCb} = S_{NCl} = 3,413 \text{ in.}^3 \).
Use $F_{yr} = 35$ ksi

$$J = \frac{Dt^3_w}{3} + \frac{b_t t^3_{fc}}{3} \left(1 - 0.63 \frac{t_{fc}}{b_c}\right) + \frac{b_t t^3_{ft}}{3} \left(1 - 0.63 \frac{t_{ft}}{b_f}\right)$$  \hspace{1cm} (AASHTO A6.3.3-9)

$$L_r = 1.95 r_t \sqrt{\frac{1}{F_{yr}}} \sqrt{\frac{1 + 6.76 \left(\frac{F_{yr} S_{xc} h}{E J}\right)^2}{1 + 6.76 \left(\frac{F_{yr} S_{xc} h}{E J}\right)^2}}$$  \hspace{1cm} (AASHTO A6.3.3-5)

$$L_r = 1.95 \left(\frac{95.6}{35}\right) \sqrt{\frac{5}{(3413)(80)}} \sqrt{1 + 6.76 \left(\frac{35 (3413)(80)}{29000 (95.6)}\right)^2}$$

$$= 449.7 \text{ in.}$$

It is noted that a conservative $L_r$ can be obtained by AASHTO Equation 6.10.8.2.3-5 as follows:

$$L_r = \pi r_t \sqrt{\frac{E}{F_{yr}}} = \left(\frac{95.6}{35}\right) \sqrt{29000} = 425.0 \text{ in.} \hspace{1cm} (AASHTO 6.10.8.2.3-5)$$

In this example, $L_r = 449.7$ in. is used.

Since $L_B = 330$ in. > $L_p = 113.2$ in., $C_B$, an equivalent uniform moment factor for lateral torsional buckling, which has a minimum value of 1.0 under the uniform moment condition, needs to be calculated. AASHTO Eq. 6.10.8.2.3-7 is only applicable to linearly varying moment diagrams between the braced points. CA Eq. 6.10.8.2.3-7 provides a more accurate solution for unbraced lengths in which the moment diagram deviates substantially from a straight line. The use of the moment envelope values at both brace points will be conservative for both single and reverse curvature. The factored moment envelope for the unbraced segment at Bent 3, 0.9$L$, and 0.8$L$ listed in Table 6.2.7-8 is shown in Figure 6.2.7-8.
In this example, the moments $M_{max}$, $M_A$, $M_B$, and $M_C$ are estimated from the factored moment envelope shown in Figure 6.2.7-8.

From Figure 6.2.7-8, at the braced point with a distance of 27.5 ft. = 330 in. from Bent 3, we obtain:

$$M = (-2749) + \left( \frac{66}{198} \right)(-6742+2749) = -4,080 \text{ kip-ft}$$

It is obvious that the absolute value of maximum moment in the unbraced segment is:

$$M_{max} = 14,263 \text{ kip-ft}$$

The absolute values of moments at the quarter point, $M_A$, at the centerline, $M_B$, at the three-quarter point, $M_C$, of the unbraced segment are calculated as follows:

$$M_A = (6742) + \left( \frac{198-82.5}{198} \right)(14263-6742) = 11,129 \text{ kip-ft}$$

$$M_B = (6742) + \left( \frac{198-165}{198} \right)(14263-6742) = 7,996 \text{ kip-ft}$$
\[ M_C = (4080) + \left( \frac{82.5}{132} \right) (6742 - 4080) = 5744 \text{ kip-ft} \]

\[ C_b = \frac{12.5 M_{\text{max}}}{2.5 M_{\text{max}} + 3 M_A + 4 M_B + 3 M_C} \]

\[ = \frac{12.5 (14263)}{2.5 (14263) + 3 (11129) + 4 (7996) + 3 (5744)} \quad \text{(CA 6.10.8.2.3-7)} \]

\[ = 1.51 \]

\[ L_p = 113.2 \text{ in.} < L_b = 330 \text{ in.} < L_r = 449.7 \text{ in.} \]

\[ M_{nc(LTB)} = C_b \left[ 1 - \left( 1 - \frac{F_y S_{xc}}{R_{pc} M_{yc}} \right) \left( \frac{L_b - L_p}{L_r - L_p} \right) \right] \frac{R_{pc} M_{yc}}{R_{pc} M_{yc}} \]

\[ = (1.51) \left[ 1 - \left( 1 - \frac{(35)(3,413)}{(1.033)(14221)(12)} \right) \left( \frac{330 - 113.2}{449.7 - 113.2} \right) \right] (1.033)(14221) \]

\[ = 17,459 \text{ kip-ft} > R_{pc} M_{yc} = 14,690 \text{ kip-ft} \quad \text{(AASHTO A6.3.3-2)} \]

Use \( M_{nc(LTB)} = 14,690 \text{ kip-ft} \)

- **Determine Flexural Resistance**
  \[ M_{nc} = \min \left( M_{nc(FLB)}, M_{nc(LTB)} \right) = \min (14,690, 14,690) = 14,690 \text{ kip-ft} \]

**Calculate Flexural Resistance – Based on Tension Flange**

Since the section is symmetric, \( R_{pl} = R_{pc}, \ M_{yl} = M_{yc} \)

\[ M_{nl} = R_{pl} M_{yl} = (1.033)(14,221) = 14,690 \text{ kip-ft} \quad \text{(AASHTO A6.4-1)} \]

**Check Design Requirement**

At the Bent 3, \( M_u = 14,263 \text{ kip-ft} \) (Table 6.2.7-19). For both compression and tension flanges:

\[ M_u = 14,263 \text{ kip-ft} < \phi \beta M_{nc} = \phi \beta M_{nl} = 14,690 \text{ kip-ft} \quad \text{O.K.} \]

\( \text{(AASHTO A6.1.1-1 & A6.1.2-1)} \)
6.2.7.11.4 Design for Shear – Strength Limit State

Select Stiffener Spacing

AASHTO C6.10.2.1.1 states that by limiting the slenderness of transversely-stiffened webs to \( D/t_w \leq 150 \), the maximum transverse stiffener spacing up to \( 3D \) is permitted. For end panels adjacent to simple supports, the stiffener spacing \( d_o \) shall not exceed \( 1.5D \) (AASHTO 6.10.9.3.3).

Try interior stiffener spacing \( d_o = 165 \) in. \( < 3D = 3(78) = 234 \) in. and end panel stiffener spacing \( d_o = 110 \) in. (for Span 1) and 100 in. (for Span 3) \( < 1.5D = 1.5(78) = 117 \) in.

Calculate Shear Resistance

Shear resistance for a stiffened interior web is as follows:

For \( d_o = 165 \) in.

\[
k = 5 + \frac{5}{(d_o / D)^2} = 5 + \frac{5}{(165 / 78)^2} = 6.12 \quad \text{(AASHTO 6.10.9.3.2-7)}
\]

\[
D_t = \frac{78}{0.625} = 124.8 \times 1.4 \sqrt{\frac{E_k}{F_{yw}}} = (1.4) \sqrt{\frac{29,000 \times 6.12}{50}} = 83.41
\]

\[
C = \frac{1.57}{(D / t_w)^2} \left( \frac{E_k}{F_{yw}} \right) = \frac{1.57 \times 29,000 \times 6.12}{124.8^2 \times 50} = 0.358 \quad \text{(AASHTO 6.10.9.3.2-6)}
\]

\[
V_p = 0.58F_{yw}D_t = 0.58(50)(78)(0.625) = 1,413.8 \text{ kip} \quad \text{(AASHTO 6.10.9.3.2-3)}
\]

\[
V_{cr} = CV_p = (0.358)(1,413.8) = 506.1 \text{ kip} \quad \text{(AASHTO 6.10.11.1.3-9)}
\]

\[
\frac{2D_t}{(b_{fc}t_{fc} + b_{ht}t_{ft})} = \frac{(2)(78)(0.625)}{(18 \times 2 + 18 \times 2)} = 1.35 \leq 2.5 \quad \text{(AASHTO 6.10.9.3.2-1)}
\]

\[
V_n = V_p \left[ C + \frac{0.87(1 - C)}{\sqrt{1 + (d_o / D)^2}} \right] = 1,413.8 \left[ 0.358 + \frac{0.87(1 - 0.358)}{\sqrt{1 + (165 / 78)^2}} \right] = 843.6 \text{ kip}
\quad \text{(AASHTO 6.10.9.3.2-2)}
\]

Check Design Requirement

\[
V_u = 754.6 \text{ kip} < \phi_n V_n = (1.0)(843.6) = 843.6 \text{ kip} \quad \text{O.K.} \quad \text{(AASHTO 6.10.9.1-1)}
\]
It is noted that for a web end panel adjacent to the simple support, \(d_o\), the first stiffener adjacent to the simple support shall not exceed \(1.5D\) (Article 6.10.9.3.3). In order to provide an anchor for the tension field in adjacent interior panels, the nominal shear strength of a web end panel shall be taken as:

\[
V_n = V_{cr} = CV_p
\]

(AASHTO 6.10.9.3.3-1)

**Check Transverse Stiffener**

The transverse stiffeners consist of plates welded or bolted to either one or both sides of the web and are required to satisfy the following requirements as specified in Article 6.10.11.1:

- **Projecting width**

\[
b_t = 7.5 \text{ in.} > 2.0 + \frac{D}{30} = 2.0 + \frac{78}{30} = 4.6 \text{ in.} \quad \text{O.K.} \quad \text{(AASHTO 6.10.11.1.2-1)}
\]

\[16t_p = (16)(0.5) = 8 \text{ in.} > b_t = 7.5 \text{ in.} > b_t / 4 = 18 / 4 = 4.5 \text{ in.} \quad \text{O.K.} \quad \text{(AASHTO 6.10.11.1.2-2)}\]

- **Moment of inertia**

For the web panels adjacent to Bent 3, \(V_u = 745.1 \text{ kip} > \phi V_{cr} = (1.0)(506.1) = 506.1 \text{ kip}\), the web tension-field resistance is required in those panels. The moment of inertia of the transverse stiffeners shall satisfy the limit specified in Article 6.10.11.1.3.

\[
I_{t1} = b t_w^3 J
\]

(AASHTO 6.10.11.1.3-3)

\[
I_{t2} = \frac{D^4 \rho_t^{1.3}}{40} \left( \frac{F_{yw}}{E} \right)^{1.5}
\]

(AASHTO 6.10.11.1.3-4)

where \(I_t\) is the moment of inertia for the transverse stiffener taken about the edge in contact with the web for single stiffeners and about the mid-thickness of the web for stiffener pairs; \(b\) is the smaller of \(d_o\) and \(D\); \(d_o\) is the smaller of the adjacent web panel widths.

\[
J = \frac{2.5}{(d_o / D)^2} - 2.0 \geq 0.5 \quad \text{AASHTO 6.10.11.1.3-5)}
\]

\(\rho_t\) is the larger of \(F_{yw} / F_{crs}\) and 1.0
\[ F_{crs} = \frac{0.31E}{(b \cdot t_p)^2} \leq F_{ys} \]  
(AASHTO 6.10.11.1.3-6)

\[ F_{ys} \] is the specified minimum yield strength of the stiffener

\[ \therefore J = \frac{2.5}{(165 / 78)^2} - 2.0 = -1.441 < 0.5 \quad \therefore \text{Use } J = 0.5 \]

\[ b = \text{smaller (} d_o = 165 \text{ in. and } D = 78 \text{ in.) = 78 in.} \]

\[ \therefore F_{crs} = \frac{0.31(29,000)}{(7.5 / 0.5)^2} = 39.96 \text{ ksi} > F_{ys} = 36 \text{ ksi} \]

Use \( F_{crs} \) = 36 ksi

\[ \rho_t = \text{larger (} F_{yw} / F_{crs} = 50 / 36 = 1.39; 1.0) = 1.39 \]

\[ l_{t1} = bt_w^3J = (78)(0.625)^3(0.5) = 9.52 \text{ in.}^4 \]

\[ l_{t2} = \frac{D^4 \rho_t}{40} \left[ \frac{F_{yw}}{E} \right]^{1.5} = \frac{(78)^4}{40} \left[ \frac{50}{29000} \right]^{1.5} = 101.6 \text{ in.}^4 \]

\[ l_t = 2 \left( \frac{7.5^3(0.5)}{12} + (7.5)(0.5) \left( 3.75 + \frac{0.625}{2} \right) \right) = 158.94 \text{ in.}^4 \]

\[ \therefore l_{t2} = 101.6 \text{ in.}^4 > l_{t1} = 9.52 \text{ in.}^4 \]

\[ l_t = 158.94 \text{ in.}^4 > l_{t1} + (l_{t2} - l_{t1}) \left( \frac{V_u - \varphi V_{cr}}{V_n - \varphi V_{cr}} \right) \]

\[ = 9.52 + (101.6 - 9.52) \left( \frac{745.1 - 506.1}{843.6 - 506.1} \right) = 74.73 \text{ in.}^4 \]

O.K.  
(AASHTO 6.10.11.1.3-7)

**6.2.7.11.5 Illustrate Calculations of Fatigue Moments and Shears**

For bridge details, fatigue moment and shear ranges are calculated and summarized in Section 6.2.7.8. For the section at Bent 3, live load moments and shears are applied to the steel section only. Fatigue moment and shear ranges are as follows:
Fatigue I:

\[ +M = \gamma (DF_m)(LL + IM)_{HL} = (1.75)(0.478)(LL + IM)_{HL} = 0.837(LL + IM)_{HL} \]

\[ -M = \gamma (DF_m)(LL + IM)_{HL} = (1.75)(0.453)(LL + IM)_{HL} = 0.793(LL + IM)_{HL} \]

\[ V = \gamma (DF_v)(LL + IM)_{HL} = (1.75)(0.7)(LL + IM)_{HL} = 1.225(LL + IM)_{HL} \]

\[ +M = 0.837(193) = 162 \text{ kip-ft} \]

\[ -M = 0.793(-1,139) = -903 \text{ kip-ft} \]

\[ \gamma(\Delta M) = 162 + 903 = 1065 \text{ kip-ft} \]

\[ \gamma(\Delta V) = 1.225(74.4 + 5.3) = 97.6 \text{ kips} \]

Fatigue II:

\[ +M = \gamma (DF_m)(LL + IM)_{pg} = (1.0)(0.478)(LL + IM)_{pg} = 0.478(LL + IM)_{pg} \]

\[ -M = \gamma (DF_m)(LL + IM)_{pg} = (1.0)(0.453)(LL + IM)_{pg} = 0.453(LL + IM)_{pg} \]

\[ V = \gamma (DF_v)(LL + IM)_{pg} = (1.0)(0.7)(LL + IM)_{pg} = 0.7(LL + IM)_{pg} \]

\[ +M = 0.478(582) = 278 \text{ kip-ft} \]

\[ -M = 0.453(-3,626) = -1,643 \text{ kip-ft} \]

\[ \gamma(\Delta M) = 278 + 1,643 = 1,921 \text{ kip-ft} \]

\[ \gamma(\Delta V) = 0.7(16 + 227.2) = 170.2 \text{ kips} \]

For special fatigue requirement for the web, factored shear, \( V_u \) due to the unfactored dead loads plus the factored fatigue load of Fatigue I for infinite life is calculated as follows:

\[ V_u = V_{dc1} + V_{dc2} + V_{dw} + (1.75)(DF_v)(LL + IM)_{HL} \]

\[ = -167.8 -13.8 -32.7 + (1.75)(0.7)(-74.4) = -305.4 \text{ kip} \]

6.2.7.11.6 Check Typical Girder Details and Web-Fatigue Limit States

Check Typical Girder Details

From CA Table 6.6.1.2.5-2, the number of stress-range cycles per truck passage for sections near interior support, \( n = 1.5 \) for Fatigue I and 1.2 for Fatigue II limit states. Nominal fatigue resistances are calculated in Table 6.2.7-25 as follows:
Fatigue I:  \( ADTT = 2,500; \quad N = (365)(75)(1.5)(0.8)(2,500) = 0.8213(10)^8 > N_{TH} \)

\[
(\Delta F_n) = (\Delta F)_{TH} \quad \text{(AASHTO 6.6.1.2.5-1)}
\]

Fatigue II:  \( ADTT = 20, \quad N = (365)(75)(1.2)(0.8)(20) = 525,600 < N_{TH} \)

\[
(\Delta F_n) = \left(\frac{A}{N}\right)^{\frac{1}{3}} \quad \text{(AASHTO 6.6.1.2.5-2)}
\]

The bending stress ranges for typical girder details Category B (Butt weld for tension flange and bolted gusset plate for lateral bracing) and Category C’ (Toe of weld for transverse stiffener) are checked as follows:

<table>
<thead>
<tr>
<th>Table 6.2.7-25 Nominal Fatigue Resistance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detail Category</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>B</td>
</tr>
<tr>
<td>C</td>
</tr>
<tr>
<td>C’</td>
</tr>
</tbody>
</table>

Fatigue I - HL-93 Truck for infinite life:

\[
\gamma(\Delta f) = \frac{\gamma(\Delta M)}{S_{NC}} = \frac{1,065(12)}{3,413} = 3.74 < 12.0 \text{ ksi O.K. for Category C’}
\]

\[
< 16.0 \text{ ksi O.K. for Category B}
\]

Fatigue II - P-9 Truck for finite life:

\[
\gamma(\Delta f) = \frac{\gamma(\Delta M)}{S_{NC}} = \frac{1,921(12)}{3,413} = 6.75 < 20.31 \text{ ksi O.K. for Category C’}
\]

\[
< 28.37 \text{ ksi O.K. for Category B}
\]

It should be pointed out that the above stresses are calculated at the extreme fiber of the top flange for Category B and can be conservatively used for Category C’. If the calculation is made at the toe of the weld for the transverse stiffeners (Category C’), the stress ranges will be smaller than the stress ranges calculated for Category B.

AASHTO 6.10.11.1.1 states that the distance between the end of the web-to-stiffener weld and the near edge of the adjacent web-to-flange weld or longitudinal stiffener-to-web weld shall not be less than \(4t_w\), but not exceed the lesser of \(6t_w\) and 4.0 in. We take this distance = \(4t_w = 4(0.625) = 2.5\) in. and assume web-to-flange weld size of 0.375 inch. The distance between the toe of the weld for the transverse stiffeners to the neutral axis is equal to \((41 – 2 – 0.375 – 2.5) = 36.125\) in.; therefore, stress ranges at the toe of the
Fatigue I - HL-93 Truck for infinite life:
\[
\gamma(\Delta f) = \frac{\gamma(\Delta M) C_{\text{toe}}}{I_{NC}} = \frac{1,065(12)(36.125)}{139,940} = 3.30 < 12.0 \text{ ksi} \text{ O.K. for Category C'}
\]

Fatigue II - P-9 Truck for finite life:
\[
\gamma(\Delta f) = \frac{\gamma(\Delta M) C_{\text{toe}}}{I_{NC}} = \frac{1,921(12)(36.125)}{139,940} = 5.95 < 20.31 \text{ ksi} \text{ O.K. for Category C'}
\]

**Check Special Fatigue Requirement for Web**

This requirement is to ensure that significant elastic flexing of the web due to shear is not to occur, and the member is able to sustain an infinite number of smaller loadings without fatigue cracking due to the shear.

\[
V_{cr} = CV_p = (0.358)(1,413.8) = 506.1 \text{ kip} > V_u = 305.4 \text{ kip} \text{ O.K.} \quad (AASHTO 6.10.5.3-1)
\]

### 6.2.7.11.7 Design Flange-to-Web Welds

Typical flange-to-web welds shown in Figure 6.2.7-9 are designed for the Strength limit states. The shear flow at the flange-to-web welds is:

\[
s_u = \frac{V_u Q}{l} = \frac{(745.1)(18)(2)(40)}{139,940} = 7.67 \text{ kip/in.}
\]

Q is the first moment of the steel flange about the neutral axis of the steel girder section. According to AASHTO Table 6.13.3.4-1, the minimum size of fillet weld for plate thickness larger than 3/4 in. is 5/16 in., but need not exceed the thickness of the thinner part jointed. Use two fillet welds \( t_w = 3/8 \) in.
Shear resistance of fillet welds (AASHTO 6.13.3.2.4b) is

\[
R_r = 0.6 \phi_{e2} F_{exx}
\]

(AASHTO 6.13.3.2.4b-1)

\(F_{exx}\) is classification strength specified of the weld metal.

Using E70XX weld metal, \(F_{exx} = 70\) ksi.

\[
R_r = 0.6 \phi_{e2} F_{exx} = (0.6)(0.8)(70) = 33.6 \text{ ksi}
\]

For two fillet welds \(t_w = 3/8\) in., shear flow resistance is

\[
s_r = (2)t_w (0.707)R_r
\]

\[
= (2)(0.375)(0.707)(33.6) = 17.82 \text{ kip/in.} > s_u = 7.67 \text{ kip/in.}
\]

∴ Use two flange-to-web welds \(t_w = 3/8\) in.

Shear resistance of the base metal of the web is

\[
R_r = 0.58 \phi A_g F_y
\]

(AASHTO 6.13.5.3-1)

For web of \(t_w = 0.625\) in., shear flow resistance is

\[
s_r = t_w (0.58) \phi_v F_y
\]

\[
= (0.625)(0.58)(1.0)(50) = 18.13 \text{ kip/in.} > s_u = 7.67 \text{ kip/in.}
\]
6.2.7.11.8  Check Requirements – Service Limit State

**Calculate Moment at Service II**

For the section at Bent 3, dead load, $DC1$, $DC2$, $DW$, and live load are applied to the noncomposite section. The factored moments at Service II for Bent 3 are as follows:

\[
M_{DC1} = -4,422 \text{ kip-ft}
\]

\[
M_{DC2} + M_{DW} = -363 + (-862) = -1,225 \text{ kip-ft}
\]

\[
M_{(LL+IM)} = (1.3)(0.834)(-3,563) = -3,863 \text{ kip-ft}
\]

**Calculate Web Bend-buckling Resistance**

\[
k = 9 \left( \frac{D}{D_c} \right)^2 = 9 \left( \frac{78}{39} \right)^2 = 36
\]

(AASHTO 6.10.1.9.1-2)

\[
F_{crw} = 0.9 E k = 0.9 \times (29,000)(36) = 60.3 \text{ ksi}
\]

(AASHTO 6.10.1.9.1-1)

\[
> \text{smaller}\left\{\begin{array}{l}
R_h F_{yc} = (1.0)(50) = 50 \text{ ksi} \\
F_{yw} / 0.7 = 50 / 0.7 = 71.4 \text{ksi}
\end{array}\right\}=50\text{ksi}
\]

Use $F_{crw} = 50$ ksi

**Check Flange Stress**

In this example, $f_t = 0$ for this interior girder. The requirement becomes:

\[
f_f = \frac{M_{DC1} + M_{DC2} + M_{DW} + M_{(LL+IM)}}{S_{NC}} \leq 0.80 R_h F_{yc} = (0.8)(1.0)(50) = 40.0 \text{ ksi}
\]

(AASHTO 6.10.4.2.2-3)

For both compression and tension flanges

\[
f_f = \frac{\left| -4,422 \right| + \left| -1,225 \right| + \left| -3,863 \right|}{3,413} = 33.4 \text{ ksi} < 40.0 \text{ksi} \quad \text{O.K.}
\]

For the compression flange

\[
f_c = 33.4 \text{ ksi} < F_{crw} = 50.0 \text{ ksi} \quad \text{O.K.} \quad \text{(AASHTO 6.10.4.2.2-4)}
\]
6.2.7.11.9 Check Requirements - Constructability

Calculate Factored Moment and Shear - Constructability

Factored moment and shear at the section of Bent 3 is as:

\[ M_u = M_{DC1} = 1.25(-4,422) = -5,528 \text{ kip-ft} \]
\[ V_u = V_{DC1} = 1.25(-167.8) = -209.8 \text{ kip} \]

Check Compression Flange

- Check Web Compactness

\[ \frac{2D_c}{t_w} = \frac{78}{0.625} = 124.8 < \lambda_{rw} = 5.7 \frac{E}{F_{yc}} = 5.7 \sqrt{\frac{29,000}{50}} = 137.3 \]

(AASHTO 6.10.1.10.2-4)

The web is noncompact, and AASHTO Equations 6.10.3.2.1-1 and 6.10.3.2.1-2 need to be satisfied.

\[ R_h = 1.0; \quad R_b = 1.0 \]

- Calculate Flexural Resistance

The nominal flexural resistance of the compression flange is the smaller of the local buckling resistance (AASHTO 6.10.8.2.2) and the lateral torsional buckling resistance (AASHTO 6.10.8.2.3).

1) Local buckling resistance

\[ \lambda_f = \frac{b_{fc}}{2t_{fc}} = \frac{18}{2(2)} = 4.5 \quad \lambda_{pf} = 0.38 \frac{E}{F_{yc}} = 0.38 \sqrt{\frac{29,000}{50}} = 9.15 \]

\[ F_{nc(LB)} = R_b R_h F_{yc} = (1.0)(1.0)(50) = 50.0 \text{ ksi} \quad \text{(AASHTO 6.10.8.2.2-1)} \]

2) Lateral torsional buckling resistance

From Section 6.2.7.11.3, we have

\[ r_t = \sqrt{\frac{b_{fc}}{12\left(1 + \frac{1}{3} \frac{D_c}{t_w} \frac{t_w}{b_{fc} t_{fc}}\right)}} = 4.7 \text{ in.} \quad \text{(AASHTO 6.10.8.2.3-9)} \]

\[ L_p = 1.0 r_t \frac{E}{F_{yc}} = 113.2 \text{ in.} \quad \text{(AASHTO 6.10.8.2.3-4)} \]

\[ F_{yr} = 35 \text{ ksi} \]
\[ L_r = \pi r \sqrt{\frac{E}{F_{yr}}} = 425.0 \text{ in.} \quad \text{(AASHTO 6.10.8.2.3-5)} \]

\[ L_p = 113.2 \text{ in.} < L_b = 330 \text{ in.} < L_r = 425.0 \text{ in.} \]

\[ F_{nc(LTB)} = C_b \left[ 1 - \left( 1 - \frac{F_{yr}}{R_h F_{yc}} \right) \frac{L_b - L_p}{L_r - L_p} \right] R_b R_h F_{yc} \leq R_b R_h F_{yc} \quad \text{(AASHTO 6.10.8.2.3-2)} \]

\[ F_{nc(LTB)} = (1.0) \left[ 1 - \left( 1 - \frac{35}{(1.0)(50)} \right) \frac{330 - 113.2}{425 - 113.2} \right] (1.0)(1.0)(50) \]

\[ = 39.6 \text{ ksi} \leq R_b R_h F_{yc} = 50 \text{ ksi} \]

Use \( F_{nc(LTB)} = 39.6 \text{ ksi} \)

It should be pointed out that the \( C_b \) factor is taken as 1.0 conservatively in the constructability check.

(3) Nominal flexural resistance

\[ F_{nc} = \min \left( F_{nc(FLB)}, F_{nc(LTB)} \right) = \min \left( 50.0, 39.6 \right) = 39.6 \text{ ksi} \]

\[ f_{bu} = \frac{M_u}{S_{Ncb}} = \frac{5,528(12)}{3,413} = 19.4 \text{ ksi} < \phi F_{nc} = 39.6 \text{ ksi} \quad \text{O.K. (AASHTO 6.10.3.2.1-2)} \]

**Calculate Web Bend-Buckling Resistance**

\[ k = 9 \left( \frac{D}{D_c} \right)^2 = 9 \left( \frac{78}{39} \right)^2 = 36 \quad \text{(AASHTO 6.10.1.9.1-2)} \]

\[ F_{crw} = \frac{0.9 E k}{ \left( \frac{D}{t_w} \right)^2} = \frac{0.9 (29,000)(36)}{ \left( \frac{78}{0.625} \right)^2} = 60.3 \text{ ksi} \quad \text{(AASHTO 6.10.1.9.1-1)} \]

\[ > \text{smaller} \begin{cases} R_h F_{yc} = (1.0)(50) = 50 \text{ ksi} \\ F_{yw} / 0.7 = 50 / 0.7 = 71.4 \text{ ksi} \end{cases} \]

Use \( F_{crw} = 50 \text{ ksi} \)

\[ f_{bu} = 19.4 \text{ ksi} < \phi F_{crw} = 50 \text{ ksi} \quad \text{O.K. (AASHTO 6.10.3.2.1-3)} \]
Check Tension Flange

\[
f_{bu} = \frac{M_u}{S_{NCL}} = \frac{5,528(12)}{3,413} = 19.4 \text{ ksi} < \phi R_y F_y = 50 \text{ ksi} \quad \text{O.K. (AASHTO 6.10.3.2.2-1)}
\]

**Check for Shear**

From Section 6.2.7.11.4, we obtain:

\[
C = 0.358, \quad V_p = 0.58 F_y W_t = 1,413.8 \text{ kip}
\]

\[
V_{cr} = CV_p = (0.358)(1,413.8) = 506.1 \text{ kip}
\]

\[
V_u = 209.8 \text{ kip} < \phi V_{cr} = (1.0)(506.1) = 506.1 \text{ kip} \quad \text{O.K. (AASHTO 6.10.3.3-1)}
\]

**6.2.7.12  Design Shear Connectors for Span 2**

The shear connectors are provided in the positive moment regions and are usually designed for fatigue and checked for strength.

**6.2.7.12.1  Design for Fatigue**

The range of horizontal shear flow, \( V_{sr} \), is as follows:

\[
V_{sr} = \frac{V_f Q}{I_{ST}} \quad \text{(6.2.7.12.1-1)}
\]

where \( V_f \) is the factored fatigue vertical shear force range as calculated in Tables 6.2.7-11 and 6.2.7-12, \( I_{ST} \) is the moment of inertia of the transformed short-term composite section, and \( Q \) is the first moment of transformed short-term area of the concrete deck about the neutral axis of the short-term composite section.

From Table 6.2.7-17, \( I_{ST} = 275,267 \text{ in.}^4 \)

\[
Q = (A_c / n)(y_c - y_{STb}) = (164.25)(88.44 - 68.51) = 3,274 \text{ in.}^3
\]

\[
V_{sr} = \frac{V_f Q}{I_{ST}} = \frac{3,274V_f}{275,267} = 0.012V_f
\]

Try \( d = 7/8 \text{ inch diameter stud, 3 per row. The fatigue shear resistance of an individual stud shear connector, } Z_r \) is as follows:

Fatigue I: \( ADTT_{SL} = p(ADTT) = (0.8)(2,500) = 2,000 > 960 \)

\[
Z_r = 5.5d^2 = 5.5(0.875)^2 = 4.21 \text{ kip} \quad \text{(AASHTO 6.10.10.2-1)}
\]

Fatigue II: \( (ADTT)_{SL} = p(ADTT) = (0.8)(20) = 16 \)
\[ N = (365)(75)(1.2)(16) = 525,600 \]

\[ \alpha = 34.5 - 4.28 \log N = 34.5 - 4.28 \log(525,600) = 10.02 \quad \text{(AASHTO 6.10.10.2-3)} \]

\[ Z_r = \alpha d^2 = 10.02(0.875)^2 = 7.67 \text{ kip} \quad \text{(AASHTO 6.10.10.2-2)} \]

For 3 - \(d = 7/8\) inch diameter studs, the required pitch of shear connectors, \(p\), is obtained as:

\[ p = \frac{n Z_r}{V_{sr}} = \frac{3Z_r}{V_{sr}} \quad \text{(AASHTO 6.10.10.1.2-1)} \]

For the positive moment region (0.2\(L\) to 0.8\(L\)) of Span 2, the detailed calculation is shown in Table 6.2.7-26.

**Table 6.2.7-26: Pitch of Shear Connectors for Span 2**

<table>

</table>

Select 3–7/8" diameter shear studs with \(F_u = 60\) ksi (AASHTO 6.4.4) at a spacing of 12" for the positive moment regions and 24" for the negative moment regions, as shown in Figure 6.2.7-10. Total number of shear studs from 0.2\(L\) to 0.8\(L\) Points in Span 2, \(n = (3)(99+1) = 300\) are provided.
AASHTO Table 6.6.1.2.3-1 requires that the base metal shall be checked for Category C when the shear studs are attached by fillet welds to the girders. From Section 6.2.7.10.5, it is seen that this requirement is satisfied.

6.2.7.12.2 Check for Strength

In this example of a straight bridge, the number of shear connectors between the point of the maximum positive moment and each adjacent point of zero moment shall satisfy the following requirement:

\[
\frac{P}{Q_r} = \left( \frac{0.85f'_c b t_s}{(A_s F_y)} \right) = \left( \frac{144}{4,021} \right) = 4,913
\]

Using unit weight of concrete \(w_c = 0.15 \text{kcf} \) and the correction factor for the source of aggregate, \(K_1 = 1.0\), the modulus of elasticity, \(E_c\), is obtained as:

\[
E_c = 120,000 (1.0) (0.15)^2 (3.6)^{0.33} = 4,120 \text{ksi}
\]

The factored shear resistance of a single \(d = 7/8 \text{ in.}\) shear stud connector is as:

\[
Q_n = 0.5A_{sc} \sqrt{f'_c E_c} = 0.5 \left( \frac{(0.875)^2 \pi}{4} \sqrt{3.6(4120)} \right)
\]

\[
= 36.6 \text{kip} > A_{sc} F_u = \frac{\pi}{4} (0.875)^2 (60) = 36.1 \text{kip}
\]

Use \(Q_n = 36.1 \text{ kip}\):

\[
n = \frac{300}{2} = 150 > \frac{P}{\phi_{ac} Q_n} = \frac{4,021}{0.85 (36.1)} = 131.0 \text{ O.K.}
\]

6.2.7.12.3 Determine Shear Connectors at Points of Contraflexure

AASHTO 6.10.10.3 requires that for members that are noncomposite for negative moment regions in the final condition, additional connectors, \(n_{ac}\) shall be placed within a distance equal to one-third of the effective concrete deck width on each side of the point of permanent load contraflexure.

\[
n_{ac} = \frac{A_s f_{sr}}{Z_r}
\]
where $f_{sr}$ is fatigue stress range in the slab reinforcement over the interior support under the Fatigue I load combination for infinite fatigue life.

As calculated in Section 6.2.7.11.5, factored Fatigue I moment range at Bent 3, $\gamma(\Delta M) = 1,065$ kips-ft. Using the elastic section property of the steel section and deck slab reinforcement calculated in Table 6.2.7-22, we obtain:

$$f_{sr} = \frac{\gamma(\Delta M)}{S_{Nstb}} = \frac{1,065(12)}{3,880} = 3.3\, \text{ksi}$$

It is noted that $f_{sr}$ can be conservatively taken as the fatigue stress range in the top flange as calculated in Section 6.2.7.11.6. In the past AASHTO Standard Specifications, $f_{sr}$ was assumed as 10 ksi.

$$n_{ac} = \frac{A_s f_{sr}}{Z_r} = \frac{13.14(3.3)}{4.21} = 10.3\, \text{studs}; \quad \text{Use 12 studs}$$

### 6.2.7.13 Design Bearing Stiffeners at Bent 3

The bearing stiffeners consist of one or more plates welded to each side of the web and extended to the full height of the web. The purpose of bearing stiffeners is to transmit the full bearing forces from factored loads. The bearing stiffeners shall be designed for axial resistance of a concentrically loaded column (Article 6.10.11.2.4) and for bearing resistance (Article 6.10.11.2.3).

#### 6.2.7.13.1 Illustrate Calculations of Factored Support Forces at Bent 3

Factored support forces for four supports at the strength limit states are summarized in Table 6.2.7-10. The calculations of factored support forces at Bent 3 are illustrated as follows:

**Dead Load**

- $R_{DC1} = 1.25(328.2) = 410.3\, \text{kip}$
- $R_{DC2} = 1.25(42.1) = 49.4\, \text{kip}$
- $R_{DW} = 1.5(64) = 96.0\, \text{kip}$

**Live Load**

- $R_{(LL+IM)HL-93} = 1.75(1.082)(249.2) = 471.9\, \text{kip}$
- $R_{(LL+IM)P15} = 1.35(1.082)(447) = 652.9\, \text{kip}$

**Controlling Support Force**

- $R_u = 410.3 + 49.4 + 96.0 + 652.9 = 1,212\, \text{kip}$
6.2.7.13.2 Select Stiffeners

For a short column, assume \( P_r = 0.85 F_{ys} A_{st} = 0.85(36)A_{st} = 30.6A_{st} \) and we obtain the initial effective column area as:

\[
A_{st} = \frac{R_u}{30.6} = \frac{1,212}{30.6} = 39.61 \text{ in.}^2
\]

Try two stiffeners, 1.875"×8" PL as shown in Figure 6.2.7-11.

6.2.7.13.3 Check Projecting Width

\[
b_L = 8 \text{ in.} < 0.48t_p \sqrt{\frac{E}{F_{ys}}} = (0.48)(1.875)\sqrt{\frac{29,000}{36}} = 25.54 \text{ in. O.K.}
\]

(AASHTO 6.10.11.2.2-1)

6.2.7.13.4 Check Bearing Resistance

Factored bearing resistance is as:

\[
(R_{sb})_r = \phi_b (R_{sb})_n = (1.0)(1.4)A_{pn}F_{ys} \quad \text{(AASHTO 6.10.11.2.3-1 and 6.10.11.2.3-2)}
\]

Assuming 1.5 in. cope on bearing stiffeners, the bearing area is:

\[
A_{pn} = (2)(8-1.5)(1.875) = 24.375 \text{ in.}^2
\]

\[
(R_{sb})_r = (1.0)(1.4)(24.375)(36) = 1,228.5 \text{ kip} > R_u = 1,212 \text{ kip} \quad \text{O.K.}
\]

Figure 6.2.7-11 Bearing Stiffeners
6.2.7.13.5 Check Axial Resistance

According to Article 6.10.11.2.4b, for stiffeners welded to the web, the effective column section consists of stiffener plates and a centrally loaded strip of the web extending not more than $9t_w$ on each side of the stiffeners.

Stiffener area: \[ A_{st} = (2)(8)(1.875) = 30 \text{ in}^2 \]

Web area:
\[ A_{web} = 
\left[ 18 \left( t_w + t_p \right) \right] = 
\left[ 18(0.625) + 1.875 \right] (0.625) = 
\left[ 13.125 \right] (0.625) = 8.20 \text{ in}^2 \]

Total effective column area: \[ A_g = 30 + 8.20 = 38.2 \text{ in}^2 \]

\[ l_{x-x} = \frac{(18)(0.625)(0.625)^3 + (1.875)(2)(8)(0.625^3)}{12} = 718 \text{ in}^4 \]

\[ r_s = \sqrt{\frac{l_{x-x}}{A_g}} = \sqrt{\frac{718}{38.2}} = 4.34 \text{ in.} \]

Use effective length factor $K = 0.75$ for the weld end connection (Article 6.10.11.2.4a), unbraced length for the bearing stiffeners $I = D = 78$ in.

\[ \frac{KL}{r_s} = \frac{0.75(78)}{4.34} = 13.5 < 120 \quad \text{O.K.} \quad \text{(AASHTO 6.9.3)} \]

Axial resistance is calculated in accordance with Article 6.9.4.1 as follows:

\[ P_e = \frac{\pi^2E}{K} A_g = \frac{\pi^2(29,000)}{(13.5)^2} (38.2) = 59,992.0 \text{ kip} \quad \text{(AASHTO 6.9.4.1.2-1)} \]

\[ P_o = F_{ys} A_g = (36)(38.2) = 1,375.2 \text{ kip} \]

\[ \therefore \frac{P_e}{P_o} = \frac{59,992.0}{1,375.2} = 43.62 > 0.44 \]

\[ \therefore P_n = \left[ 0.658 \left( \frac{P_o}{P_e} \right) \right] P_o = \left[ 0.658 \left( \frac{1,375.2}{59,992.0} \right) \right] (1,375.2) = 1,362.1 \text{ kip} \]

(AASHTO 6.9.4.1.1-1)
\[ P_r = \phi_c P_n = (0.9)(1362.1) = 1,225.9 \text{ kip} > R_u = 1,212 \text{ kip} \quad \text{O.K.} \]

\[ \therefore \text{Use two 1.875"} \times 8" \text{ PL bearing stiffeners} \]

### 6.2.7.13.6 Design Bearing Stiffener-to-Web Welds

Fillet welds are usually used for bearing stiffener-to-web connections. According to AASHTO Table 6.13.3.4-1, the minimum size of fillet weld for thicker plate thickness joined larger than 3/4 in. is 5/16 in., but need not exceed the thickness of the thinner part joined. Try two fillet welds \( t_w = 5/16 \) in. on each stiffener.

Shear resistance of fillet welds (Article 6.13.3.2.4) is

\[ R_r = 0.6 \phi_{e2} F_{e,x} \quad \text{(AASHTO 6.13.3.2.4-1)} \]

Using E70XX weld metal, \( F_{e,x} = 70 \text{ ksi} \).

\[ R_r = 0.6 \phi_{e2} F_{e,x} = (0.6)(0.8)(70) = 33.6 \text{ ksi} \]

The total length of welds, allowing 2.5 inches for clips at both the top and bottom of the stiffener, is:

\[ L = 78 - 2(2.5) = 73 \text{ in.} \]

The total shear resistance of welds connecting the bearing stiffeners to the web is:

\[ V_r = (4)(0.707) t_w L R_r \]

\[ = (4)(0.707)(0.3125)(73)(33.6) = 2,168 \text{ kip} > V_u = 1,212 \text{ kip} \quad \text{O.K.} \]

\[ \therefore \text{Use two fillet welds } t_w = 3/8 \text{ in. on each stiffener} \]

It should be noted that it is common practice to have the ¼" hold backs on the fillet welds of stiffeners as shown in Caltrans Bridge Standard Details (XS), xs1-410-2 and xs1-410-3 (Caltrans, 2017).
### 6.2.7.14 Design Intermediate Cross Frames

An intermediate cross frame consisting of single angles is selected, as shown in Figure 6.2.7-12.

![Figure 6.2.7-12 A Typical Intermediate Cross Frame](image)

#### 6.2.7.14.1 Calculate Wind Load

Design wind pressure is determined as:

\[
P_Z = 2.56 \times 10^{-6} V^2 K_Z G C_D
\]  

(AASHTO 3.8.1.2.1-1)

\( V = \) design 3-second gust wind speed = 110 mph (AASHTO Table 3.8.1.1.2-1)

Since the bridge is located in an urban area, the ground surface roughness is B (Article 3.8.1.1.4), and it is classified as Wind Exposure Category B (Article 3.8.1.1.5). Assume the top of the superstructure is 45 ft above the ground, i.e., \( Z = 45 \) ft.

The pressure exposure and elevation coefficient, \( K_Z \), for Strength III and Service IV load combinations is obtained:

\[
K_Z (B) = \left[ \frac{2.5 \ln \left( \frac{Z}{0.9834} \right) + 6.87}{345.6} \right]^2 = \left[ \frac{2.5 \ln \left( \frac{45}{0.9834} \right) + 6.87}{345.6} \right]^2 = 0.781
\]  

(AASHTO 3.8.1.2.1-2)

The gust effect factor \( G \) is taken as 1.0 (AASHTO Table 3.8.1.2.1-1). The drag coefficient \( C_D \) is taken as 1.3 (AASHTO Table 3.8.1.2.1-2).

\[
P_Z = 2.56 \times 10^{-6} (110)^2 (0.781)(1.0)(1.3) = 0.031 \text{ ksf}
\]  

(AASHTO 3.8.1.2.1-1)
In this example, the midspan girder depth $d = 80.75 \text{ in.} = 6.73 \text{ ft}$

Depth of deck and barrier = $12.25 + 42 = 54.25 \text{ in.} = 4.52 \text{ ft}$.

Wind load acting on the girder span is as:

$$WS_{girder} = P_Z (4.52 + 6.73) = (0.031)(11.25) = 0.349 \text{ kip/ft}$$

Wind load acting on the bottom flange is as:

$$WS_{bf} = WS_{girder} \left( \frac{d / 2}{(4.52 + 6.73)} \right) = \frac{(0.349)(6.73/2)}{11.25} = 0.104 \text{ kip/ft}$$

Wind force acting on top flange (directly transmitted to the concrete deck)

$$WS_t = 0.349 - 0.104 = 0.245 \text{ kip/ft}$$

6.2.7.14.2 Check Flexural Resistance of Bottom Flange

For cross frame spacing, $L_b = 27.5 \text{ ft}$, wind induced moment applied on the bottom flange of the exterior girder is estimated as:

$$M_{WS} = \frac{WS_{bf} L_b^2}{10} = \frac{(0.104)(27.5)^2}{10} = 7.87 \text{ kip-ft} \quad (\text{AASHTO C4.6.2.7.1-2})$$

For the smaller bottom flange with $t_f = 1.75 \text{ in.}$, wind induced lateral stress is:

$$f_{i-WS} = \frac{M_{WS}}{t_f b_f^2 / 6} = \frac{(7.87)(12)}{(1.75)(18)^2 / 6} = 1.0 \text{ ksi}$$

From CA Table 3.4.1, the load combinations Strength III and V are:

For Strength III: $1.25 DC + 1.5 DW + 1.4 WS$

For Strength V: $1.25 DC + 1.5 DW + 1.35 DF(LL+IM)_{HL-93} + 0.4 WS$

It is obvious that Strength V controls design. In this example, the section at the 0.5 Point of Span 2 is checked. From Table 6.2.7-8, Factored moments about the major axis of the cross section are as follows:

$$1.25M_{DC1} = 3,269 \text{ kip-ft}; \quad 1.5M_{DC2} = 420 \text{ kip-ft}$$

$$M_{DW} = 765 \text{ kip-ft}; \quad M_{(LL+IM)_{HL-93}} = 1.35(0.805)(3455) = 3,755 \text{ kip-ft}$$

$$M_u = 3269 + 420 + 765 + 3755 = 8,209 \text{ kip-ft}$$
The factored lateral bending stress in the bottom flange due to wind load is:

\[ f_l = (0.4)f_{l,WS} = (0.4)(1.0) = 0.4 \text{ ksi} < 0.6F_{yf} = 30 \text{ ksi} \text{ O.K. (AASHTO 6.10.1.6-1)} \]

At the strength limit state, the composite compact section in positive moment regions shall satisfy the requirement as follows:

\[ M_u + \frac{1}{3}f_lS_{xt} \leq \phi_fM_n \]  
(AASHTO 6.10.7.1.1-1)

where \( S_{xt} = \frac{M_{yt}}{F_{yt}} \)

From Section 6.2.7.10.3, \( M_{yt} = 15,274 \) kip-ft and \( M_n = 19,856 \) kip-ft

\[ S_{xt} = \frac{M_{yt}}{F_{yt}} = \frac{15274(12)}{50} = 3,666 \text{ in.}^3 \]

\[ M_u + \frac{1}{3}f_lS_{xt} = 8209 + \frac{1}{3}(0.4)\frac{3666}{12} = 8,250 \text{ kip-ft} \text{ O.K.} \]

\[ \leq \phi_fM_n = 19,856 \text{ kip-ft} \]

6.2.7.14.3 Calculate Forces Acting on the Cross Frame

In order to find forces acting in the cross frame members, a cross frame is treated like a truss with tension diagonals only and solved using statics. The wind force in the top strut is assumed to be zero because the diagonals will transfer the wind load directly into the deck slab. The horizontal wind forces applied to the brace points are assumed to be carried fully by the bottom strut in the exterior bays. Therefore, the bottom strut in all bays will be conservatively designed for this force.

At Strength III limit state, the factored wind force acting on the bottom strut is:

\[ P_u = 1.4WS_{by}L_b = (1.4)(0.104)(27.5) = 4.0 \text{ kip} \]

Factored force acting on diagonals is:

\[ P_u = \frac{4.0}{\cos\phi} = \frac{4.0}{\sqrt{5.5^2 + 6^2}} = 5.43 \text{ kip} \]
6.2.7.14.4 Design Bottom Strut

Select Section

Try L 6×6×1/2 as shown in Figure 6.2.7-13.

\[ A_g = 5.77 \text{ in.}^2; \quad I_x = I_y = 19.9 \text{ in.}^4; \quad r_x = r_y = 1.86 \text{ in.} \]

\[ x = y = 1.67 \text{ in.}; \quad r_z = 1.18 \text{ in.}; \quad \tan \alpha = 1.0 \]

![Figure 6.2.7-13 Single Angle for Bottom Strut](image)

Check Limiting Effective Slenderness Ratio

Article 6.9.3 requires that the effective slenderness ratio, \( KL/r \) shall not exceed 140 for compression bracing members. For buckling about the minor principal axis (Z-Z), using unbraced length \( L_z = 6 \text{ ft} = 72 \text{ in.} \) and effective length factor \( K = 1.0 \) for single angles regardless of end conditions (Article 4.6.2.5), the effective slenderness ratio is:

\[
\frac{KL_z}{r_z} = \frac{(1.0)(72)}{1.18} = 61 < 140 \quad \text{O.K.}
\]

For out-plane buckling about the vertical geometric axis (y-y), using unbraced length \( L_y = 12 \text{ ft} = 144 \text{ in.} \) and effective length factor \( K = 1.0 \), the effective slenderness ratio is:

\[
\frac{KL_y}{r_y} = \frac{(1.0)(144)}{1.86} = 77.4 < 140 \quad \text{O.K.}
\]

Check Member Strength

Since a single angle member is connected through one leg only, the member is subjected to combined flexural moments about principal axes due to eccentrically applied axial load and axial compression. Article 6.9.4.4 states that single angles subjected to combined axial compression and flexure may be designed as axially loaded compression members in accordance with Articles 6.9.2.1, 6.9.4.1.1, and 6.9.4.1.2, as appropriate, using one of
the effective slenderness ratios specified by Article 6.9.4.4, provided that: (1) end connections are to a single leg of the angle, and are welded or use minimum two-bolt connections; (2) angles are loaded at the ends in compression through the same one leg; and (3) there are no intermediate transverse loads. It is obvious that the bottom strut meets those three conditions and can be designed in accordance with Article 6.9.4.4.

- **Determine Effective Slenderness Ratio**

  For equal-leg angles that are individual members, \[ \frac{L}{r_x} = \frac{(144)}{1.86} = 77 < 80 \]

  \[ \left( \frac{KL}{r} \right)_{eff} = 72 + 0.75 \frac{L}{r_x} = 72 + (0.75) \frac{144}{1.86} = 130 \quad \text{(AASHTO 6.9.4.4-1)} \]

- **Check Slenderness of Element**

  \[ \frac{b}{t} = \frac{6}{0.5} = 12 < \lambda_r = 0.45 \sqrt[3]{\frac{29,000}{36}} = 12.8 \quad \text{(AASHTO 6.9.4.2.1-1)} \]

  L 6×6×1/2 is a nonslender element cross section.

- **Determine Nominal Axial Compression Strength**

  Axial resistance is calculated in accordance with AASHTO 6.9.4.1 as follows:

  \[ P_e = \frac{\pi^2 E}{KL} \frac{A_g}{r_s} = \frac{\pi^2 (29,000)}{(130)^2} (5.77) = 97.72 \text{ kip} \quad \text{(AASHTO 6.9.4.1.2-1)} \]

  \[ P_o = F_y A_g = (36)(5.77) = 207.72 \text{ kip} \]

  \[ \frac{P_e}{P_o} = \frac{97.72}{207.72} = 0.47 > 0.44 \]

  \[ P_n = \begin{bmatrix} 0.658 \\ \frac{P_e}{P_o} \end{bmatrix} P_o = \begin{bmatrix} 0.658 \\ \frac{207.72}{97.72} \end{bmatrix} (207.72) = 85.33 \text{ kip} \quad \text{(AASHTO 6.9.4.1.1-1)} \]

- **Check Compressive Strength**

  \[ P_u = 4.0 \text{ kip} < \phi_c P_n = (0.9)(85.33) = 76.70 \text{ kip} \quad \text{O.K.} \]
6.2.7.14.5 Design Diagonal

Select Section

Try $L 4\times 4\times 5/16, A_g = 2.4 \text{ in.}^2, r_{min} = 0.781 \text{ in.}$

$L = \sqrt{5.5^2 + 6^2} = 8.14 \text{ ft} = 98 \text{ in.}$

Check Limiting Effective Slenderness Ratio

$$\frac{KL}{r_{min}} = \frac{(1.0)(98)}{0.791} = 123.9 < 140$$

O.K. (AASHTO 6.9.3)

Check Member Strength

A separate calculation similar to the above bottom strut design shows that angle $L 4\times 4\times 5/16$ meets specification requirements.

6.2.7.14.6 Design Top Strut

Since the force in the top strut is assumed to be zero, we select an angle $L 6\times 6\times 1/2$ to provide lateral stability to the top flange during construction and to design for 2 percent of the flange yield strength. The design calculation is similar to the above for the bottom strut and is not illustrated here.

6.2.7.14.7 Design Connection of Bottom Strut

Determine Design Load

For end connections of diaphragms and cross frames in straight girder bridges, Article 6.13.1 requires that they shall be designed for the calculated member forces. In this example, the connection of the bottom strut is designed for the calculated member load, $P_u = 4.0 \text{ kip}$.

Determine the Number of Bolts Required

- Select Bolts

Try ASTM F3125 Grade A325 high-strength 3/4 in. diameter bolt with threads excluded from the shear plane, with bolt spacing of 3 in. and edge distance of 1.75 in. For 3/4 in. diameter bolts, the minimum spacing of bolts is $3d = 2.25 \text{ in.}$ (Article 6.13.2.6.1), and the minimum edge distance is 1.0 in. (AASHTO Table 6.13.2.6.6-1).

- Determine Nominal Resistance per Bolt
Calculate nominal shear resistance in single shear

\[ R_n = 0.56 A_b F_{ub} N_s \]  
(AASHTO 6.13.2.7-1)

\[ A_b = \left( \frac{0.75}{2} \right)^2 \pi = 0.442 \text{ in.}^2 \]

\[ F_{ub} = 120 \text{ ksi} \]  
(AASHTO 6.4.3)

\[ N_s = 1 \quad \text{(for single shear)} \]

\[ R_n = 0.56 A_b F_{ub} N_s = (0.56)(0.442)(120)(1) = 29.7 \text{ kip} \]  
(AASHTO 6.13.2.7-1)

Calculate the design bearing strength for each bolt on stiffener material

Since the clear edge distance, \( L_c = 1.75 - (0.75 + 0.0625)/2 = 1.344 \text{ in.} \) is less than \( 2d = 1.5 \text{ in.} \) and stiffener material is A709 Grade 36, \( F_u = 58 \text{ ksi} \).

\[ R_n = 1.2 L_c t F_u = 1.2(1.344)(0.5)(58) = 46.8 \text{ kip} \]  
(AASHTO 6.13.2.9-2)

- **Determine design strength per bolt**

  It is obvious that shear controls and nominal shear resistance per bolt, \( R_n = 29.7 \text{ kip} \).

- **Determine the Number of Bolts Required**

  The number of bolts required is:

  \[ N = \frac{P_u}{\phi_s R_n} = \frac{4.0}{(0.8)(29.7)} = 0.17 \text{ bolts} \]

  Use 2 bolts as shown in Figure 6.2.7-14.
6.2.7.15 Design Bolted Field Splices

6.2.7.15.1 General Design Requirements

For flexural members, splices shall preferably be made at or near points of dead load contraflexure in continuous spans and at points of the section change. Article 6.13.6.1.4a states that bolted splices for flexural members shall be designed using slip-critical connections as specified by Article 6.13.2.1.1. The general design requirements are:

- Factored resistance of splices shall not be less than 100 percent of the smaller factored resistances of the section spliced at the strength limit state (CA 6.13.1).

- Slip shall be prevented at the Service II limit state (Article 6.13.2.1.1) and during the erection of the steel girders, and during the casting or placing of the deck (Article 6.13.6.1.3a).

- Base metal at the gross section shall be checked for Category B at the fatigue limit state (AASHTO Table 6.6.1.2.3-1).

As shown in Figure 6.2.7-4, bolted field girder splices for Span 2 are located approximately at the 0.3 and the 0.7 Points. In the following, the design of a bolted splice (Figure 6.2.7-15) as a slip-critical connection at the 0.7 Point will be illustrated. Oversized or slotted holes shall not be used (Article 6.13.6.1.3a). The hole diameter used in the calculation shall be 1/16 in. larger than the nominal diameter as shown in AASHTO Table 6.13.2.4.2-1.
6.2.7.15.2 Design Bottom Flange Splices

Try one outer splice plate 1 in. × 18 in., two inner plates 1-1/8 in. × 8 in. and one fill plate ¼ in. × 18 in. as shown in Figure 6.2.7-16.

Try Grade A325 high-strength $d = 7/8$ in. bolt threads excluded with a bolt spacing of 3 in. and edge distance of 2 in. For 7/8 in. diameter bolts, the minimum spacing of bolts is $3d = 2.625$ in. (Article 6.13.2.6.1), and the minimum edge distance is 1.125 in. (AASHTO Table 6.13.2.6.6-1). The standard hole size for a $d = 7/8$ in. bolt is 0.9375 in. (AASHTO Table 6.13.2.4.2-1).
Determine Number of Bolts Required – Strength Limit States

- Determine Design Forces

\[ P_{fy} = F_{fy} A_e \quad \text{(AASHTO 6.13.6.1.3b-1)} \]

where \( A_e \) is the smaller effective area for the flange on either side of the splice.

\[ A_e = \left( \frac{\phi_u F_u}{\phi_y F_{yf}} \right) A_n \leq A_g \quad \text{(AASHTO 6.13.6.1.3b-2)} \]

Try 4 – 7/8 in. diameter/row for the flange splices. For smaller flange, we have:

\[ A_n = \left[ 18 - (4)(0.9375) \right](1.75) = 24.94 \text{ in}^2 \]

\[ A_g = (18)(1.75) = 31.5 \text{ in}^2 \]
\[
A_e = \left( \frac{\phi_u F_u}{\phi_f F_{fy}} \right) A_n = \left( \frac{(0.8)(65)}{(0.95)(50)} \right) (24.94) = 27.30 \text{ in.}^2 < A_g = 31.5 \text{ in.}^2
\]

Use \( A_e = 27.30 \text{ in.}^2 \)

\[
P_{fy} = F_{fy} A_e = (50)(27.30) = 1,365.0 \text{ kip}
\]

- **Determine Nominal Resistance per Bolt**

  When the length between the extreme fasteners measured parallel to the line of action of the force is less than 50 in., the nominal shear resistance for a Grade A325 – 7/8 in. diameter bolt is:

  \[
  R_n = 0.56 A_b F_{ub} N_s 
  \]  

  \[
  A_b = \left( \frac{0.875}{2} \right)^2 \pi = 0.6 \text{ in.}^2 
  \]  

  \[
  F_{ub} = 120 \text{ ksi} 
  \]  

  \[
  N_s = 2 \quad \text{(for double shear)} 
  \]  

  \[
  R_n = (0.56)(0.6)(120)(2) = 80.6 \text{ kip}
  \]

  Since the clear end distance \( L_c = 1.875 - 0.469 = 1.41 \text{ in.} < 2d = 1.75 \text{ in.} \) (Figure 6.2.7-16), the nominal bearing resistance for each bolt hole on flange material is:

  \[
  R_n = 1.2 L_c t F_u 
  \]  

  \[
  R_n = (1.2)(1.41)(1.75)(65) = 192.5 \text{ kip}
  \]

  It is obvious that shear resistance controls and design resistance per bolt, \( R_n = 80.6 \text{ kip} \).

- **Evaluate Fill Plate Effects**

  Article 6.13.6.1.4 specifies that fillers \( \frac{1}{4} \text{ inch} \) and thicker need not be extended and developed provided that the factored shear resistance of the bolts at the strength limit state is reduced by the reduction factor \( R \).

  \[
  R = \frac{1 + \gamma}{1 + 2\gamma} 
  \]  

  \[
  (\text{AASHTO 6.13.6.1.4-1})
  \]
\[ \gamma = \frac{A_f}{A_p} \]

- \( A_f \) = sum of the area of the fillers on both sides of the connected plate
- \( A_p \) = smaller of either the connected plate area or the sum of the splice plate areas on both sides of the connected plate

\[ \begin{align*}
A_f &= (0.25)(18) = 4.5 \text{ in.}^2 \\
A_p &= \text{smaller of } \left\{ \begin{array}{l}
(1.75)(18) = 31.5 \text{ in.}^2 \\
2(1.125)(8) + (1)(18) = 36.0 \text{ in.}^2 
\end{array} \right. \\
&= 31.5 \text{ in.}^2 \\
\gamma &= \frac{A_f}{A_p} = \frac{4.5}{31.5} = 0.143 \\
R &= \frac{1 + \gamma}{1 + 2\gamma} = \frac{1 + 0.143}{1 + 2(0.143)} = 0.889 \quad \text{(AASHTO 6.13.6.1.4-1)}
\]

- Determine the Number of Bolts Required

The number of bolts required is:

\[ N = \frac{P_{fy}}{\phi_s R R_n} = \frac{1,365.0}{(0.8)(0.889)(80.6)} = 23.81 \text{ bolts} \]

Use 28 bolts as shown in Figure 6.2.7-16.

**Check Slip Resistance of Bolts – Service II Limit State and Constructability**

Articles 6.13.2.1.1 and 6.13.6.1.3a require that the bolted connections shall be proportioned to prevent slip at the Service II limit state and during the erection of the steel and during the casting or placing of the deck.

- Determine Factored Moments

For Service II, factored moment at the 0.7 Point of Span 2 is obtained from Table 6.2.7-13.

\[ +M_u = 1434 + 194 + 280 + 2784 = 4,692 \text{ kip-ft} \]
\[ -M_u = 1434 + 194 + 280 - 1094 = 814 \text{ kip-ft} \]

For constructability, factored dead load moment during the casting of the deck at
the 0.7 Point of Span 2 is obtained as:

\[ M_{DL} = (1.0) (1434) = 1,434 \text{ kip-ft} \]

It is clear that the Service II moment governs the design.

- **Check Slip Resistance**

Assume a non-composite section conservatively at the splice location and use the smaller section property for the bottom flange \( S_{Ncb} = 2,837 \text{ in.}^3 \) (Table 6.2.7-15).

\[
f_s = \frac{M_u / S_{Ncb}}{R_h} = \frac{4692(12)/2837}{1.0} = 19.85 \text{ ksi}
\]

\[ R_u = F_s A_g = (19.85)(31.5) = 625.3 \text{ kip} \]

Nominal slip resistance per bolt is:

\[ R_n = K_h K_s N_s P_t \text{ (AASHTO 6.13.2.8-1)} \]

where \( K_h \) is the hole size factor and is equal to 1.0 for the standard hole (AASHTO Table 6.13.2.8-2); \( K_s \) is the surface condition factor and is taken at 0.5 for Class B surface condition (AASHTO Table 6.13.2.8-3); \( P_t \) is the minimum required bolt tension and is equal to 39 kips (AASHTO Table 6.13.2.8-1). According to Article 6.13.2.2, factored slip resistance of 28 bolts is:

\[ R_r = R_n = (1.0)(0.5)(2)(39)(28) = 1,092 \text{ kip} > R_u = 625.3 \text{ kip} \quad \text{O.K.} \]

**Check Tensile Resistance of Splice Plates**

Since areas of the inner and outer plates are the same, the flange design force is assumed to be divided equally to the inner and outer plates. In the following, splice plates are checked for yielding on the gross section, fracture on the net section, and block shear rupture (Article 6.13.4).

- **Yielding on Gross Section**

\[ A_g = (18)(1.0) + (2)(8)(1.125) = 36 \text{ in.}^2 \]

\[ P_r = \phi_y A_g F_y = (0.95)(36)(50) = 1,710.0 \text{ kip} \text{ (AASHTO 6.8.2.1-1)} \]

\[ P_r = 1,710.0 \text{ kip} > P_{fy} = 1,365.0 \text{ kip} \quad \text{O.K.} \]

- **Fracture on Net Section**
Inner plates:

\[ A_n = (2) \left[ 8 - (2)(0.9375) \right](1.125) = 13.78 \text{ in.}^2 \]

\[ P_r = \phi_u F_u A_n U = (0.8) (65)(13.78)(1.0) = 716.6 \text{ kip} \quad \text{(AASHTO 6.8.2.1-2)} \]

\[ P_r = 716.6 \text{ kip} > \frac{P_{fy}}{2} = \frac{1,365.0}{2} = 682.5 \text{ kip} \quad \text{O.K.} \]

Outer plate:

\[ A_n = \left[ 18 - (4)(0.9375) \right](1.0) = 14.25 \text{ in.}^2 \]

\[ P_r = \phi_u F_u A_n U = (0.8) (65)(14.25)(1.0) = 741.0 \text{ kip} \quad \text{(AASHTO 6.8.2.1-2)} \]

\[ P_r = 741.0 \text{ kip} > \frac{P_{fy}}{2} = 682.5 \text{ kip} \quad \text{O.K.} \]

- **Block Shear Rupture**

Assume bolt holes are drilled full size, reduction factor for a hole, \( R_p \) is taken equal to 1.0 (Article 6.13.4). For flange splice plates, the reduction factor for block shear rupture, \( U_{bs} \) is taken equal to 1.0 (Article 6.13.4). Bolt pattern and block shear rupture failure planes on the inner and outer splice plates are shown in Figure 6.2.7-17.

Inner plates:

\[ A_{tn} = 2 \left[ 6 - 1.5(0.9375) \right](1.125) = 10.34 \text{ in.}^2 \]

\[ A_{vn} = 2 \left[ 20 - 6.5(0.9375) \right](1.125) = 31.29 \text{ in.}^2 \]

\[ A_{vg} = 2(20)(1.125) = 45.0 \text{ in.}^2 \]

\[ F_u A_{vn} = (65)(31.29) = 2,033.9 \text{ kip} < F_y A_{vg} = (50)(45.0) = 2,250.0 \text{ kip} \]

\[ R_r = \phi_{bs} R_p \left( 0.58 F_u A_{vn} + U_{bs} F_u A_{tn} \right) \]

\[ = 0.8(1.0) \left[ (0.58)(65)(31.29) + (1.0)(65)(10.34) \right] = 1,481.4 \text{ kip} \quad \text{(AASHTO 6.13.4-1)} \]

\[ R_r = 1,481.4 \text{ kip} > \frac{P_{fy}}{2} = 682.5 \text{ kip} \quad \text{O.K.} \]

Outer plate:

\[ A_{tn} = 2 \left[ 6 - 1.5(0.9375) \right](1.0) = 9.19 \text{ in.}^2 \]
\[ A_{vn} = 2 \left[ 20 - 6.5(0.9375) \right](1.0) = 27.81 \text{ in.}^2 \]
\[ A_{vg} = 2(20)(1.0) = 40.0 \text{ in.}^2 \quad \text{(AASHTO 6.13.4-1)} \]
\[ F_u A_{vn} = (65)(27.81) = 1,807.7 \text{ kip} < F_y A_{vg} = (50)(40.0) = 2,000.0 \text{ kip} \]
\[ R_r = \phi_{bs} R_p \left( 0.58 F_u A_{vn} + U_{bs} F_u A_{in} \right) \]
\[ = 0.8(1.0) \left[ (0.58)(65)(27.81) + (1.0)(65)(9.19) \right] = 1,316.6 \text{ kip} \]
\[ \text{(AASHTO 6.13.4-1)} \]

\[ R_r = 1,316.6 \text{ kip} > \frac{P_{fy}}{2} = 682.5 \text{ kip} \quad \text{O.K.} \]

**Figure 6.2.7-17 Block Shear Rupture - Bottom Flange Splice Plates**

**Check Fracture on Net Section and Block Shear Rupture for Flange**

- Fracture on Net Section
  
  Since the design force is actually based on fracture resistance on the net section, there is no need to check.

- Block Shear Rupture
Bolt pattern and block shear rupture failure planes on the bottom flange are assumed in Figure 6.2.7-18.

\[
\begin{align*}
A_{tn} &= 2 \left[ 6 - 1.5 \left( 0.9375 \right) \right] (1.75) = 16.08 \text{ in.}^2 \\
A_{vn} &= 2 \left[ 19.875 - 6.5 \left( 0.9375 \right) \right] (1.75) = 48.23 \text{ in.}^2 \\
A_{vg} &= 2(19.875)(1.75) = 69.56 \text{ in.}^2 \\
\therefore F_u A_{vn} &= (65)(48.23) = 3,135.0 \text{ kip} < F_y A_{vg} = (50)(69.56) = 3,478.0 \text{ kip} \\
R_r &= \phi_{bs} R_p \left( 0.58 F_u A_{vn} + U_{bs} F_u A_{in} \right) \\
&= 0.8 \left( 1.0 \right) \left[ (0.58) (65)(48.23) + (1.0) (65)(16.08) \right] = 2,290.8 \text{ kip} \\
R_r &= 2,290.8 \text{ kip} > P_{fy} = 1,365.0 \text{ kip} \quad \text{O.K.}
\end{align*}
\]

**Check Fatigue for Splice Plates**

Fatigue stress ranges in base metal of the bottom flange splice plates adjacent to the slip-critical connections are checked for Category B (AASHTO Table 6.6.1.2.3-1). Fatigue normally does not govern the design of splice plates when the combined area of inner and outer splice plates is larger than the area of the smaller flange spliced. The fatigue moment ranges at the 0.7 Point of Span 2 are obtained from Tables 6.2.7-11 and 6.2.7-12. The nominal fatigue resistance is calculated in Table 6.1.8-2 in Chapter 6.1. The flexural stresses at the edges of the splice plates are assumed to be the same as the flexural stresses in the girder at those locations. The gross section of the smaller girder section is used to calculate the stresses. Properties of the steel section alone are used conservatively. For the smaller spliced section (Table 6.2.7-15), \( S_{Ncb} = 2,837 \text{ in.}^3 \)

Fatigue I - HL-93 Truck for infinite life:
\[ \gamma(\Delta f) = \frac{\gamma(\Delta M)}{S_{NCb}} = \frac{1,440(12)}{2,837} = 6.09 \text{ ksi} < 16.0 \text{ ksi} \quad \text{O.K. for Category B} \]

Fatigue II - P-9 Truck for finite life:

\[ \gamma(\Delta f) = \frac{\gamma(\Delta M)}{S_{NCb}} = \frac{2,396(12)}{2,837} = 10.13 \text{ ksi} < 30.15 \text{ ksi} \quad \text{O.K. for Category B} \]

### 6.2.7.15.3 Design Top Flange Splices

Try one outer splice plate 5/8 in. × 18 in., two inner plates 3/4 in. × 8 in., and one fill plate 1 in. × 18 in. as shown in Figure 6.2.7-19.

As the same as the bottom flange, try Grade A325 high-strength \( d = 7/8 \) in. bolt threads excluded with a bolt spacing of 3 in. and edge distance of 2 inches.

**Determine Number of Bolts Required – Strength Limit State**

- Determine Design Forces
  
  Try 4 – 7/8 in. diameter/row for the flange splices. For the smaller flange, we have:
  
  \[ A_n = \left[ 18 - (4)(0.9375) \right](1.0) = 14.25 \text{ in.}^2 \]
  
  \[ A_y = (18)(1.0) = 18 \text{ in.}^2 \]

  \[ \therefore A_e = \left( \frac{\phi_yF_y}{\phi_yF_y} \right) A_n = \left( \frac{(0.8)(65)}{(0.95)(50)} \right)(14.25) = 15.60 \text{ in.}^2 < A_y = 18 \text{ in.}^2 \]

  \( \text{(AASHTO 6.13.6.1.3b-2)} \)

  Use \( A_e = 15.60 \text{ in.}^2 \)

  \[ P_{fy} = F_yA_e = (50)(15.6) = 780.0 \text{ kip} \]

  \( \text{(AASHTO 6.13.6.1.3b-1)} \)
Figure 6.2.7-19 Top Flange Splice

- **Determine Nominal Resistance per Bolt**

  As calculated in Section 6.2.7.15.2, the nominal shear resistance per Grade A325 – 7/8 in. diameter bolt in double shear is:

  \[ R_n = 80.6 \text{ kip} \]

  The nominal bearing resistance for each bolt hole on flange material is:

  \[ R_n = 1.2L_c t F_u \]  \hspace{1cm} (AASHTO 6.13.2.9-2)

  For exterior hole:

  \[ L_c = 1.875 - 0.469 = 1.41 \text{ in.} \]

  \[ R_n = (1.2)(1.41)(1.0)(65) = 110.0 \text{ kip} \]

  It is obvious that shear resistance controls and design resistance per bolt, \( R_n = 80.6 \text{ kips} \).

- **Evaluate Fill Plate Effects**

  Article 6.13.6.1.4 specifies that fillers ¼ inch and thicker need not be extended and
developed provided that the factored shear resistance of the bolts at the strength limit state is reduced by the reduction factor \( R \).

\[
A_f = (1.0)(18) = 18 \text{ in.}^2
\]

\[
A_p = \text{smaller of } \left\{ \begin{array}{l}
1.0(18) = 18\text{ in.}^2 \\
2(0.75)(8) + (0.625)(18) = 23.25\text{ in.}^2
\end{array} \right\} = 18\text{ in.}^2
\]

\[
\gamma = \frac{A_f}{A_p} = \frac{18.0}{18.0} = 1.0
\]

\[
R = \frac{1 + \left( \frac{A_f}{A_p} \right)}{1 + 2\left( \frac{A_f}{A_p} \right)} = \frac{1 + 18/18}{1 + 2(18/18)} = 0.667
\]  
(AASHTO 6.13.6.1.4-1)

**Determine Number of Bolts Required**

The number of bolts required is:

\[
N = \frac{P_{fy}}{\phi_s R_R R_n} = \frac{780.0}{(0.8)(0.667)(80.6)} = 18.14 \text{ bolts}
\]

Use of 20 bolts shown in Figure 6.2.7-19 is OK.

**Check Slip Resistance of Bolts – Service II Limit State and Constructability**

From Section 6.2.7.15.2, the moment at Service II is 4,692 kip-ft. Assume non-composite section conservatively at the splice location and use the smaller section property for the top flange \( S_{NCt} = 2,193 \text{ in.}^3 \) (Table 6.2.7-15). Slip force is calculated as follows:

\[
f_s = \frac{M_u}{S_{NCt}} = \frac{4692(12)}{2193} = 25.67 \text{ ksi}
\]

\[
R_u = f_s A_g = (25.67)(18) = 462.1 \text{ kip}
\]

The nominal slip resistance per bolt is:

\[R_n = K_n K_s N_s P_t\]  
(AASHTO 6.13.2.8-1)

Slip resistance of 20 bolts is:

\[
R_r = R_n = (1.0)(0.5)(2)(39)(20) = 780.0 \text{ kip} > R_u = 462.1 \text{ kip} \quad \text{O.K.}
\]
Check Tensile Resistance of Splice Plates

Since areas of the inner and outer plates differ by less than 10%, the flange design force is assumed to be divided equally to the inner and outer plates. In the following, splice plates are checked for yielding on the gross section, fracture on the net section, and block shear rupture (Article 6.13.4).

- Yielding on Gross Section

\[ A_g = (18)(0.625) + (2)(8)(0.75) = 23.25 \text{ in.}^2 \]

\[ P_r = \phi_y A_g F_y = (0.95)(23.25)(50) = 1,104.4 \text{ kip} \quad \text{(AASHTO 6.8.2.1-1)} \]

\[ P_r = 1,104.4 \text{ kip} > P_{fy} = 780.0 \text{ kip} \quad \text{O.K.} \]

- Fracture on Net Section

Inner plates:

\[ A_n = (2)[8 - (2)(0.9375)](0.75) = 9.19 \text{ in.}^2 \]

\[ P_r = \phi_u F_u A_n = (0.8)(65)(9.19)(1.0) = 477.9 \text{ kip} \quad \text{(AASHTO 6.8.2.1-2)} \]

\[ P_r = 477.9 \text{ kip} > \frac{P_{fy}}{2} = \frac{780.0}{2} = 390.0 \text{ kip} \quad \text{O.K.} \]

Outer plate:

\[ A_n = [18 - (4)(0.9375)](0.625) = 8.91 \text{ in.}^2 \]

\[ P_r = \phi_u F_u A_n = (0.8)(65)(8.91)(1.0) = 463.3 \text{ kip} \quad \text{(AASHTO 6.8.2.1-2)} \]

\[ P_r = 463.3 \text{ kip} > \frac{P_{fy}}{2} = 390.0 \text{ kip} \quad \text{O.K.} \]

- Block Shear Rupture

The bolt pattern and block shear rupture failure planes on the inner and outer splice plates are assumed in Figure 6.2.7-20.

Inner Plates:

\[ A_{tn} = 2[6 - 1.5(0.9375)](0.75) = 6.89 \text{ in.}^2 \]

\[ A_{vn} = 2[14 - 4.5(0.9375)](0.75) = 14.67 \text{ in.}^2 \]
\[ A_{vg} = 2(14)(0.75) = 21.0 \text{ in.}^2 \]

\[ \therefore F_u A_{vn} = (65)(14.67) = 953.6 \text{kip} < F_y A_{vg} = (50)(21.0) = 1050.0 \text{kip} \]

\[ R_r = \phi_{bs} \rho_p \left( 0.58 F_u A_{vn} + U_{bs} F_u A_{tn} \right) \]

\[ = 0.8(1.0) \left[ (0.58)(65)(14.67) + (1.0)(65)(6.89) \right] = 800.7 \text{ kip} \]

(AASHTO 6.13.4-1)

\[ R_r = 800.7 \text{ kip} > \frac{P_{fy}}{2} = 390.0 \text{ kip} \quad \text{O.K.} \]

---

**Figure 6.2.7-20 Block Shear Rupture – Top Flange Splice Plates**

**Outer plate:**

\[ A_{tn} = 2 \left[ 6 - 1.5(0.9375) \right](0.625) = 5.74 \text{ in.}^2 \]

\[ A_{vn} = 2 \left[ 14 - 4.5(0.9375) \right](0.625) = 12.23 \text{ in.}^2 \]

\[ A_{vg} = 2(14)(0.625) = 17.5 \text{ in.}^2 \]
\[ F_u A_{vn} = (65)(12.23) = 795.0 \text{ kip} < F_y A_{vg} = (50)(17.5) = 875.0 \text{ kip} \]

\[ R_r = \phi_{bs} R_p (0.58 F_u A_{vn} + U_{bs} F_u A_{in}) \]
\[ = 0.8(1.0)[(0.58)(65)(12.23) + (1.0)(65)(5.74)] = 667.3 \text{ kip} \]

(AASHTO 6.13.4-1)

\[ R_r = 667.3 \text{ kip} > \frac{P_{fy}}{2} = 390.0 \text{ kip} \quad \text{O.K.} \]

**Check Fracture on Net Section and Block Shear Rupture for Flange**

- **Fracture on Net Section**
  
  Since the design force is actually based on fracture resistance on the net section, there is no need to check.

- **Block Shear Rupture**
  
  The bolt pattern and block shear rupture failure planes on the inner and outer splice plates are assumed in Figure 6.2.7-21.

![Figure 6.2.7-21 Block Shear Rupture – Top Flange](image)

\[ A_{tn} = 2 \left[ 6 - 1.5(0.9375) \right](1.0) = 9.19 \text{ in.}^2 \]

\[ A_{vn} = 2 \left[ 13.875 - 4.5(0.9375) \right](1.0) = 19.31 \text{ in.}^2 \]

\[ A_{vg} = 2(14)(1.0) = 28.0 \text{ in.}^2 \]

\[ F_u A_{vn} = (65)(19.31) = 1,255.2 \text{ kip} < F_y A_{vg} = (50)(28.0) = 1,400.0 \text{ kip} \]
Check Fatigue for Splice Plates

Fatigue stress ranges in base metal of the top flange splice plates adjacent to the slip-critical connections are checked for Category B (AASHTO Table 6.1.2.3-1). The fatigue moment ranges at the 0.7 Point are obtained from Tables 6.2.7-11 and 6.2.7-12. The nominal fatigue resistance is calculated in Table 6.1.8-2 in Chapter 6.1. The flexural stresses at the edges of the splice plates are assumed to be the same as the flexural stresses in the girder at those locations. The gross section of the smaller girder section is used to calculate the stresses. Properties of the steel section alone are used conservatively. For the smaller spliced section (Table 6.2.7-15), $S_{NCl} = 2,193$ in.$^3$.

**Fatigue I - HL-93 Truck for infinite life:**

$$
\gamma(\Delta f) = \frac{\gamma(\Delta M)}{S_{NCl}} = \frac{1,440(12)}{2,193} = 7.88 \text{ ksi} < 16.0 \text{ ksi} \quad \text{O.K. for Category B}
$$

**Fatigue II - P-9 Truck for finite life:**

$$
\gamma(\Delta f) = \frac{\gamma(\Delta M)}{S_{NCb}} = \frac{2,396(12)}{2,193} = 13.11 \text{ ksi} < 30.15 \text{ ksi} \quad \text{O.K. for Category B}
$$

6.2.7.15.4 Design Web Splices

Try two $7/16$ in. $\times$ 64 in. web splice plates and Grade A325 high-strength $d = 7/8$ in. bolt threads excluded with bolt spacing of 3 in. as shown in Figure 6.2.7-15.

$$
A_g = (2)(0.4375)(64) = 56 \text{ in.}^2
$$

Check Bolt Shear Resistance - Strength II Limit States

- Calculate Design Forces (CA 6.13.6.1.3c)
  - Case 1: Factored shear resisted by the web
    - The smaller factored shear resistance of the web at the point of splice is obtained from Section 6.2.7.11.4 as follows:
      $$
      V_{uw} = \phi V_n = 843.6 \text{ kip}
      $$
      - Moment induced by eccentrically loaded shear is
\[ M_{vw} = V_{uw} e = (843.6)(6.5) = 5,483 \text{ kip-in.} \]

Case I design forces are shown in Figure 6.2.7-22a.

Case 2: Factored plastic moment resisted by the web

At the strength limit state, the portion of the smaller total factored plastic moment carried by the web is shown in Figure 6.2.7-22b. To determine the plastic moment, we need to calculate the location of the PNA as follows:

Top flange: \( t_f = 1.0 \text{ in.}; \ b_f = 18 \text{ in.} \)

\[ P_t = t_f b_f F_{fy} = (1.0)(18)(50) = 900 \text{ kip} \]

Web: \( t_w = 0.625 \text{ in.}; \ D = 78 \text{ in.} \)

\[ P_w = t_w DF_{fw} = (0.625)(78)(50) = 2,437.5 \text{ kip} \]

Bottom flange: \( t_c = 1.75 \text{ in.}; \ b_c = 18 \text{ in.} \)

\[ P_c = t_c b_c F_{fy} = (1.75)(18)(50) = 1,575 \text{ kip} \]

Since \( P_t = 900 \text{ kip} \neq P_c = 1,575 \text{ kip} \), the plastic neutral axis (PNA) is within the web. Denote that \( \bar{y} \) is the distance from the top of the web to the PNA as shown in Figure 6.2.7-23, by the plastic force equilibrium, we obtain:

\[ P_t + (\bar{y})t_w F_{yw} = P_c + (D - \bar{y})t_w F_{yw} \]

\[ \bar{y} = \frac{P_w + P_c - P_t}{2t_w F_{yw}} = \frac{2437.5 + 1575 - 900}{2(0.625)(50)} = 49.8 \text{ in.} \]

\[ y_o = \frac{D}{2} - \bar{y} = \frac{78}{2} - 49.8 = -10.8 \text{ in.} \] (CA C6.13.6.1.3c-3)
The portion of the smaller total factored plastic moment carried by the web is:

\[ M_{uw} = \frac{t_w F_{yw}}{4} (D^2 - 4y_o^2) \]

\[ = (1.0) \left( \frac{0.625}{4} \right) \left( 78^2 - (4)(-10.8)^2 \right) \quad \text{(CA C6.13.6.1.3c-1)} \]

\[ = 43,886 \text{ kip-in} \]

\[ H_{uw} = \phi_f (2t_w y_o F_{yw}) \]

\[ = (1.0)(2)(0.625)(-10.8)(50) = -675 \text{ kip} \quad \text{(CA C6.13.6.1.3c-2)} \]

Case 1 – Factored Shear
(b) Case 2—Factored Plastic Moment

**Figure 6.2.7-22 Design Forces for Web Splices**

- **Determine Nominal Resistance per Bolt**

  As calculated in Section 6.2.7.15.2, the nominal shear resistance per Grade A325 – 7/8 in. diameter bolt in double shear is:

  \[ R_n = 80.6 \text{ kip} \]
The nominal bearing resistance for each bolt hole on web material is:

\[ R_n = 1.2L_c t F_u \]  

(AASHTO 6.13.2.9-2)

For exterior hole:

\[ L_c = 1.875 - 0.469 = 1.41 \text{ in.} \]

\[ R_n = (1.2)(1.41)(0.625)(65) = 68.7 \text{ kip} \]

It is obvious that bearing resistance controls and nominal resistance per bolt is 68.7 kip. It is noted that Article 6.13.2.7 specifies that the nominal shear resistance of a fastener in connections whose length between extreme fasteners measured parallel to the line of action of the force is greater than 38 in. in length shall be taken 0.83 times the value given by Articles 6.13.2.7-1 and 6.13.2.7-2. Since the resultant shear applied to the bolts is mainly induced by the horizontal force and the length between extreme fasteners in the horizontal direction is less than 38 in. shear resistance of the bolt is not reduced.

- Calculate Polar Moment of Inertia \( I_p \) of Bolts with Respect to Neutral Axis of Web Section

It can be seen that the upper and lower right corner bolts are the most highly stressed and will be investigated. The “Vector” method is used to calculate shear force \( R \) on the top right bolt.

\[ I_p = \sum x^2 + \sum y^2 \]

\[ = (2)(4)(30^2 + 27^2 + 24^2 + 21^2 + 18^2 + 15^2 + 12^2 + 9^2 + 6^2 + 3^2) \]

\[ + (2)(21)(4.5^2 + 1.5^2) = 28,665 \text{ in.}^2 \]

- Check Shear Resistance of Lower Right Corner Bolt

Case 1 – Factored shear resistance resisted by the web

Factored shear force applied on the lower right corner bolt is:

\[ R_x = \frac{M_{ww}y}{I_p} = \frac{5483(30)}{28665} = 5.74 \text{ kip} \quad (\rightarrow) \]

\[ R_y = \frac{M_{ww}x}{I_p} = \frac{5483(4.5)}{28665} = 0.86 \text{ kip} \quad (\uparrow) \]
\[ R_v = \frac{V_{uw}}{4(21)} = \frac{843.6}{84} = 10.04 \text{ kip} \ (\uparrow) \]

\[ R_h = 0 \]

\[ R_{bolt} = \sqrt{(R_h + R_x)^2 + (R_v + R_y)^2} \]
\[ = \sqrt{(0 + 5.74)^2 + (10.04 + 0.86)^2} \]
\[ = 12.32 \text{ kip} < \phi_{bb} R_n = (0.8)(68.7) = 54.96 \text{ kip} \quad \text{O.K.} \]

Case 2 - Factored plastic moment resisted by the web

Factored shear forces applied on the lower right corner bolt are:

\[ R_x = \frac{M_{uw} y}{I_p} = \frac{43886(30)}{28665} = 45.93 \text{ kip} \ (\rightarrow) \]

\[ R_y = \frac{M_{uw} x}{I_p} = \frac{43886(4.5)}{28665} = 6.89 \text{ kip} \ (\downarrow) \]

\[ R_v = 0 \]

\[ R_h = \frac{H_{uw}}{4(21)} = \frac{675}{84} = 8.04 \text{ kip} \ (\rightarrow) \]

\[ R_{bolt} = \sqrt{(R_h + R_x)^2 + (R_v + R_y)^2} \]
\[ = \sqrt{(8.04 + 45.93)^2 + (0 + 6.89)^2} \quad \text{O.K.} \]
\[ = 54.41 \text{ kip} < \phi_{bb} R_n = (0.8)(68.7) = 54.96 \text{ kip} \]

**Check Slip of Bolts – Service II Limit State and Constructability**

- Calculate Design Forces (CA 6.13.6.1.3c)

Case 1 – Factored shear

From Table 6.2.7-2, factored shear at the 0.7 Point of Span 2 at Service II is obtained

\[ V_u = V_{DC1} + V_{DC2} + V_{DW} + (1.3)DF_v (LL + IM)_{HL-93} \]
\[ = (-68.8) + (-8.7) + (-13.4) + (1.3)(1.082)(-92.7) = -221.3 \text{ kip} \]
Moment due to eccentrically loaded shear is:

\[ M_{vw} = V_u e = (221.3)(6.5) = 1,438.5 \text{ kip-in.} \]

**Case 2 – Factored moment resisted by web**

From Section 6.2.7.15.2, factored moment at the 0.7 Point of Span 2 at Service II is:

\[ +M_u = 1434 + 194 + 280 + 2784 = 4,692 \text{ kip-ft} \]

Moment resisted by the web at Service II

\[ M_{uw} = \frac{t_w D^2}{12} \left| f_s - f_{os} \right| \quad \text{(CA C6.13.6.1.3c-4)} \]

**Case 2** is larger flexural stress due to Service II at the inner fiber of the flange under consideration for the smaller section at the point of splice (positive for tension and negative for compression), and \( f_{os} \) is flexural stress at the inner fiber of the other flange of the smaller section at the point of splice concurrent with \( f_s \) (positive for tension and negative for compression).

In this example, flexural stresses at the extreme fiber of the flange are used conservatively.

\[ f_s = \frac{M_u}{S_{NCt}} = \frac{4692(12)}{2193} = 25.68 \text{ ksi} \quad \text{(Compression)} \]

\[ f_{os} = \frac{M_u}{S_{NCb}} = \frac{4692(12)}{2837} = 19.85 \text{ ksi} \quad \text{(Tension)} \]

\[ M_{uw} = \frac{t_w D^2}{12} \left| f_s - f_{os} \right| \]

\[ = \frac{(0.625)(78)^2}{12} \left| 25.68 - 19.85 \right| \quad \text{(CA C6.13.6.1.3c-4)} \]

\[ = 14,427.3 \text{ kip-in.} \]
Horizontal force at web

\[ H_{uw} = \frac{t_w D}{2}(f_s + f_{os}) \]

\[ = \frac{(0.625)(78)}{2}(-25.68 + 19.85) \]

\[ = -142.1 \text{ kip} \quad \text{(CA C6.13.6.1.3c-5)} \]

- Calculate Factored Shear Forces Applied on Upper Right Corner Bolt

**Case 1 – Factored shear**

\[ R_x = \frac{M_{uw}y}{I_p} = \frac{1438.5(30)}{28665} = 1.51 \text{ kip} \quad (\leftarrow) \]

\[ R_y = \frac{M_{uw}x}{I_p} = \frac{1438.5(4.5)}{28665} = 0.23 \text{ kip} \quad (\uparrow) \]

\[ R_v = \frac{V_{uw}}{(4)(21)} = \frac{221.3}{84} = 2.63 \text{ kip} \quad (\uparrow) \]

\[ R_h = 0 \]

\[ R_{bolt} = \sqrt{(R_h + R_x)^2 + (R_v + R_y)^2} \]

\[ = \sqrt{(0+1.51)^2 + (2.63+0.23)^2} \]

\[ = 3.23 \text{ kip} \]

**Case 2 – Factored moment resisted by web**

\[ R_x = \frac{M_{uw}y}{I_p} = \frac{(14427.3)(30)}{28665} = 15.10 \text{ kip} \quad (\leftarrow) \]

\[ R_y = \frac{M_{uw}x}{I_p} = \frac{(14427.3)(4.5)}{28665} = 2.26 \text{ kips} \quad (\uparrow) \]

\[ R_v = 0 \]

\[ R_h = \frac{H_{uw}}{4(21)} = \frac{142.1}{84} = 1.69 \text{ kips} \quad (\leftarrow) \]
\[ R_{\text{bolt}} = \sqrt{(R_t + R_x)^2 + (R_v + R_y)^2} \]
\[ = \sqrt{(1.69 + 15.1)^2 + (0 + 2.26)^2} \]
\[ = 16.9 \text{ kip} \]

- **Check Slip Resistance**

  From Section 6.2.7.15.2, the slip resistance of one bolt is:

  \[ R_r = R_n = (1.0)(0.5)(2)(39) = 39.0 \text{ kip} > R_{\text{bolt}} = 16.9 \text{ kip} \]

  O.K.

**Check Splice Plates**

- **Check Shear Resistance at the Strength Limit States**

  (1) **Yielding on the gross section:**

  \[ V_r = \phi_v (0.58A_g F_{yw}) = (1.0)(0.58)(2 \times 0.4375 \times 64)(50) \]

  \[ = 1,624 \text{ kip} > V_{uw} = 843.6 \text{ kip} \]

  O.K.

  (2) **Fracture on net section:**

  \[ A_n = 2 \left[ 64 - 21(0.9375) \right] (0.4375) = 38.77 \text{ in.}^2 \]

  \[ V_r = \phi_u (0.58F_u A_n) = (0.8)(0.58)(65)(38.77) \]

  \[ = 1,169.3 \text{ kip} > V_{uw} = 843.6 \text{ kip} \]

  O.K.

(3) **Block shear rupture**

The bolt pattern and block shear rupture failure planes on the inner and outer splice plates are assumed in Figure 6.2.7-24.
Figure 6.2.7-24 Block Shear Rupture – Web Splice Plates

\[ A_{tn} = 2 \left[ 8 - 2.5(0.9375) \right](0.4375) = 4.95 \text{ in}^2 \]

\[ A_{vn} = 2 \left[ 62 - 20.5(0.9375) \right](0.4375) = 37.43 \text{ in}^2 \]

\[ A_{vg} = 2(62)(0.4375) = 54.25 \text{ in}^2 \]

\[ F_u A_{vn} = (65)(37.43) = 2,433.0 \text{ kip} < F_y A_{vg} = (50)(54.25) = 2,712.5 \text{ kip} \]

\[ R_r = \phi_{bs} R_p (0.58F_u A_{vn} + U_{bs}F_u A_{ln}) = 0.8(1.0) \left( [0.58(65)(37.43) + (1.0)(50)(4.95)] \right) = 1,326.9 \text{ kip} \]

(AASHTO 6.13.4-1)

\[ R_r = 1,326.9 \text{ kip} > V_{uw} = 843.6 \text{ kip} \quad \text{O.K.} \]

- Check Flexural Resistance

Factored plastic moment resistance of the splice plates is

\[ \phi M_n = (1.0) M_p = (1.0) \left( 2 \frac{(0.4375)(64)^2}{4} \right) (50) \]

\[ = 44,800 \text{ kip-in.} > M_{uw} = 43,886 \text{ kip-in.} \quad \text{O.K.} \]

**Check Fatigue Stress Ranges**

From AASHTO Table 6.6.1.2.3-1, Category B shall be used for base metal at the gross section of the high-strength bolted slip-critical resistant section. Similar assumptions used
for flange splices are used for the web splice plates. Flexural stress ranges at the web splice plates are induced by the positive-negative fatigue moments and moments due to the eccentricity of the fatigue shear forces from the centerline of the splices to the center of gravity of the web-splice bolt group. Positive moments are assumed to be applied to the short-term composite section, and negative moments are assumed to be applied to the steel section alone in the splice location. Eccentric moments of the fatigue shear forces are assumed to be applied to the gross section of the web splice plates. For the smaller spliced section, $I_{NC} = 99,872$ in.$^4$ (Table 6.2.7-15), and $I_{ST} = 275,267$ in.$^4$ (Table 6.2.7-17). For the web splice plates, as shown in Figure 6.2.7-22, the elastic section modulus for the short-term composite section, the steel section only, and the web splice plates are calculated as follows:

$$S_{ST-wb} = \frac{I_{ST}}{C_{splice-bot}} = \frac{275267}{(Y_{STb} - t_{bf} - 7)} = \frac{275267}{(68.51 - 1.75 - 7)} = 4,606 \text{ in.}^3$$

$$S_{ST-wt} = \frac{I_{ST}}{C_{splice-top}} = \frac{275267}{(Y_{STt} - t_{tf} - 7)} = \frac{275267}{(12.24 - 1.0 - 7)} = 64,921 \text{ in.}^3$$

$$S_{NC-wb} = \frac{I_{NC}}{C_{splice-bot}} = \frac{99872}{(Y_{NCb} - t_{bf} - 7)} = \frac{99872}{(35.2 - 1.75 - 7)} = 3,776 \text{ in.}^3$$

$$S_{NC-wt} = \frac{I_{NC}}{C_{splice-top}} = \frac{99872}{(Y_{NCT} - t_{tf} - 7)} = \frac{99872}{(45.55 - 1.0 - 7)} = 2,660 \text{ in.}^3$$

$$S_{w-splice} = (2)(0.4375)(64)^2 \left(\frac{6}{6}\right) = 597 \text{ in.}^3$$

It is seen that the bottom edge of the web splice plate obviously controls design and is, therefore, checked. Flexural stress ranges due to fatigue moments (Tables 6.2.7-11 and 6.2.7-12) and eccentric moments of the fatigue shear forces (Tables 6.2.7-11 and 6.2.7-12) are:

**Fatigue I - HL-93 Truck for infinite life:**

$$\gamma(\Delta f) = \left[\frac{+M}{S_{ST-wb}}\right] + \left[\frac{-M}{S_{NC-wb}}\right] + \left[\frac{[(+V)-(V)]e}{S_{w-splice}}\right]$$

$$= \frac{(1042)(12)}{4606} + \frac{(398)(12)}{3776} + \frac{(16.5+60.8)(5)}{597}$$

$$= 2.71 + 1.26 + 0.65 = 4.62 \text{ ksi} < 16.0 \text{ ksi} \text{ O.K. for Category B}$$
Fatigue II - P-9 Truck for finite life:

\[
\gamma(\Delta f) = \frac{+M}{S_{ST-\text{wb}}} + \frac{-M}{S_{NC-\text{wb}}} + \frac{[(+V) - (-V)]e}{S_{w-\text{splice}}} \\
= \frac{(1693)(12)}{4606} + \frac{(703)(12)}{3776} + \frac{(21.1 + 97.9)(5)}{597} \\
= 4.41 + 2.23 + 1.00 = 7.64 \text{ ksi} < 30.15 \text{ ksi} \quad \text{O.K. for Category B}
\]

6.2.7.16 Calculate Deflection and Camber

6.2.7.16.1 Determine Stiffness of Girders

Article 2.5.2.6.2 specifies that for composite design, the stiffness of the design cross-section used for the determination of deflection should include the entire width of the roadway and the structurally continuous portions of the railing, sidewalks, and median barriers. Article 6.10.1.5 states that the stiffness properties of the steel section alone for the loads applied to noncomposite sections, the stiffness properties of the long-term composite section for permanent loads applied to composite sections, and the stiffness properties of the short-term composite section properties for transient loads shall be used over the entire bridge length, respectively.

In this example, section properties of the steel section alone, the short-term section, and the long-term composite sections are calculated in Tables 6.2.7-15 to 6.2.7-18, and Tables 6.2.7-21 to 6.2.7-24.

6.2.7.16.2 Calculate Vehicular Load Deflections

Article 2.5.2.6.2 specifies that the maximum absolute deflection of the straight girder systems should be based on all design lanes loaded by HL93, including dynamic load allowance (Service I load combination) and all supporting components deflected equally.

Number of Traffic Lanes = (Deck Width - Barrier Width)/12
\[
= (58 - 2 \times 1.75) / 12 = 4.54
\]

Number of design traffic lanes = 4

For this five-girder bridge, each girder will carry 0.8 design traffic lane equally. Assume that the exterior girders have the same section properties as the interior girders, and use properties of the short-term composite sections of interior girders, as shown in Tables 6.2.7-17 and 6.2.7-18. Vehicular live load deflections are calculated and listed in Table 6.2.7-27. Comparisons with Article 2.5.2.6.2 requirement of the vehicular load deflection limit L/800 are also made in Table 6.2.7-27.
Table 6.2.7-27 Live Load Deflections for Interior Girder

6.2.7.16.3 Calculate Camber

For a steel-concrete composite girder, camber is the curvature/deformation induced by a fabrication process to achieve its designed deck profile grade under full dead load and normal temperature. BDM 6.11 (Caltrans, 2021b) addresses camber components and camber diagrams for a steel-concrete composite girder. The screed camber and web camber diagrams, including individual components, are required to be shown on design plans.

The screed camber is the recommended amount that the screed grade must be raised above the designed deck profile grade for the deck pours to achieve the designed grade. It includes components of deck dead load, deck shrinkage, and added dead load.

The web camber is the adjustment to the girder geometry during fabrication in a horizontal or no-load condition. It includes all seven camber components of, deck dead load, deck shrinkage, added dead load, girder dead load, vertical curve, horizontal curve, and additional camber.

Deck dead load and girder dead load deflections are due to the weight of the deck slab, stay-in-place deck form, and steel girder, respectively. For unshored construction, it is assumed that all deck concrete is placed at once, and deck slab dead load and steel girder dead load are applied to the steel girder section alone (Tables 6.2.7-15 and 6.2.7-21). Deck shrinkage should be taken as 10 percent of the deflection due to the deck slab dead load per BDM 6.11 (Caltrans 2021b).

Added Dead Load deflection is due to the weight of the curb, railing, utilities, and future AC overlay. Added dead load is applied to the long-term composite section girder (Tables 6.2.7-18 and 6.2.7-24).

BDM 6.11 requires that the screed camber and web camber diagrams, including individual components for each girder, be shown on design plans.
Figure 6.2.7-25 shows the camber diagram of the interior girder.

![Camber Diagram of Interior Girder](image)

**Figure 6.2.7-25  Camber Diagram of Interior Girder**

### 6.2.7.17 Identify and Designate Steel Bridge Members and Components

A new term, the System Redundant Member (SRM), is introduced in the *AASHTO BDS*, 8th Edition (AASHTO, 2017). It is a member traditionally designated as an FCM for which the redundancy is not apparent by engineering judgment but is demonstrated to have redundancy through a refined analysis. At the design stage, a refined analysis to identify SRMs is not required per STP 6.1 (Caltrans, 2019c).

It is the bridge designer’s responsibility to identify a bridge member as a Fracture Critical Member (FCM), a Primary Member, or a Secondary Member in designing a new steel bridge and to designate or tabulate them explicitly on the contract documents (plans and/or special provisions). STP 6.1 (Caltrans, 2019c) provides a policy for the identification of steel members for steel bridges. BDM 6.1 (Caltrans, 2021c) provides examples for showing steel bridge member designations on the plans.
Figure 6.2.7-26 shows the member designations of steel girders for this bridge.

Notes:

$T$ – Primary Tension Member (Non-Fracture Critical)
$C$ – Primary Compression Member

$T$ and $C$ zones shown extend to the middle depth of the web.

Figure 6.2.7-26 Member Designations
NOTATION

\( A \) = fatigue detail category constant
\( ADTT \) = average daily truck traffic in one direction over the design life
\( ADTT_{SL} \) = single lane ADTT
\( A_b \) = area of the bolt corresponding to the nominal diameter (in.\(^2\))
\( A_c \) = cross section area of concrete deck slab (in.\(^2\))
\( A_e \) = effective area (in.\(^2\))
\( A_f \) = sum of area of the fillers on both sides of the connected plate (in.\(^2\))
\( A_g \) = gross cross section area (in.\(^2\))
\( A_i \) = area of the component \( i \) (in.\(^2\))
\( A_n \) = net cross section area (in.\(^2\))
\( A_p \) = smaller of either the connected plate area or the sum of the splice plate areas on both sides of the connected plate (in.\(^2\))
\( A_s \) = reinforcement area; total area of longitudinal reinforcement over the interior support within the effective concrete deck width (in.\(^2\))
\( A_{sc} \) = cross-sectional area of a stud shear connector (in.\(^2\))
\( A_{st} \) = cross-sectional area of a stiffener (in.\(^2\))
\( A_{tn} \) = net area along the cut carrying tension stress in block shear (in.\(^2\))
\( A_{vg} \) = gross area along the cut carrying shear stress in block shear (in.\(^2\))
\( A_{vn} \) = net area along the cut carrying shear stress in block shear (in.\(^2\))
\( A_{web} \) = web area of effective section of a bearing stiffener (in.\(^2\))
\( b_{eff} \) = effective flange width (in.)
\( b_f \) = full width of the flange (in.)
\( b_{fc} \) = full width of a compression flange (in.)
\( b_{ft} \) = full width of a tension flange (in.)
\( b_t \) = width of the projecting stiffener element (in.)
\( C \) = ratio of the shear-buckling resistance to the shear yield strength;
\( C_b \) = moment gradient modifier
\( C_D \) = drag coefficient
\( CG \) = centroid of gravity
\( CG_{NC} \) = centroid of gravity axis of the noncomposite steel section
\( D \) = web depth (in.)
\( D_c \) = web depth in compression at the elastic range (in.)
\[ D_{cp} = \text{web depth in compression at the plastic moment (in.)} \]
\[ D_p = \text{distance from the top of the concrete deck to the neutral axis of the composite sections at the plastic moment (in.)} \]
\[ D_t = \text{total depth of the composite section (in.)} \]
\[ d = \text{total depth of the steel section; nominal diameter of the bolt (in.)} \]
\[ d_s = \text{distance from plastic neutral axis to the midthickness of the concrete deck used to compute the plastic moment (in.)} \]
\[ d_t = \text{distance from plastic neutral axis to the midthickness of the tension flange used to compute the plastic moment (in.)} \]
\[ d_w = \text{distance from plastic neutral axis to the middepth of the web used to compute the plastic moment (in.)} \]
\[ d_o = \text{transverse stiffener spacing (in.)} \]
\[ DC = \text{dead load of structural components and nonstructural attachments} \]
\[ DC1 = \text{structural dead load, acting on the non-composite section} \]
\[ DC2 = \text{nonstructural dead load, acting on the long-term composite section} \]
\[ DF_m = \text{live load distribution factor for moments} \]
\[ DF_v = \text{live load distribution factor for shears} \]
\[ DW = \text{dead load of wearing surface} \]
\[ E = \text{modulus of elasticity of steel (ksi)} \]
\[ E_c = \text{modulus of elasticity of concrete (ksi)} \]
\[ e_g = \text{distance between CG of the concrete deck slab and CG of noncomposite section (in.)} \]
\[ F_{crw} = \text{nominal bend-buckling resistance of webs (ksi)} \]
\[ F_{exx} = \text{classification strength specified of the weld metal (ksi)} \]
\[ F_{nc} = \text{nominal flexural resistance of the compression flange (ksi)} \]
\[ F_{nc(FLB)} = \text{nominal flexural resistance based on compression flange local buckling (kip-in.)} \]
\[ F_{nc(LTB)} = \text{nominal flexural resistance based on compression flange lateral torsional buckling (kip-in.)} \]
\[ F_{nt} = \text{nominal flexural resistance of the tension flange (ksi)} \]
\[ F_u = \text{specified minimum tensile strength of steel (ksi)} \]
\[ F_{ub} = \text{specified minimum tensile strength of bolt (ksi)} \]
\[ F_y = \text{specified minimum yield strength of steel (ksi)} \]
\[ F_{yc} = \text{specified minimum yield strength of a compression flange (ksi)} \]
\[ F_{yf} = \text{specified minimum yield strength of a flange (ksi)} \]
\( F_{yr} = \) compression-flange stress at the onset of nominal yielding including residual stress effects, taken as the smaller of \( 0.7F_{yc} \) and \( F_{yw} \) but not less than \( 0.5F_{yc} \) (ksi)

\( F_{ys} = \) specified minimum yield strength of a stiffener (ksi)

\( F_{yt} = \) specified minimum yield strength of a tension flange (ksi)

\( F_{yw} = \) specified minimum yield strength of a web (ksi)

\( f_c' = \) specified minimum concrete strength (ksi)

\( f_{bu} = \) flange stress calculated without consideration of the flange lateral bending (ksi)

\( f_c = \) longitudinal compressive stress in concrete deck without considering flange lateral bending (ksi)

\( f_f = \) stress in flanges and cover plates at the service II limit state (ksi)

\( f_i = \) flange lateral bending stress (ksi)

\( f_{i-WS} = \) wind load induced flange lateral stress (ksi)

\( f_{os} = \) flexural stress at the inner fiber of the other flange of the smaller section at the point of splice concurrent with \( f_s \) (positive for tension and negative for compression) (ksi)

\( f_s = \) larger flexural stress due to Service II at the inner fiber of the flange under consideration for the smaller section at the point of splice (positive for tension and negative for compression) (ksi)

\( f_{sr} = \) fatigue stress range (ksi)

\( G = \) gust effect factor

\( h = \) depth between centerline of flanges (in.)

\( I = \) moment of inertia of a cross section (in.\(^4\))

\( I_{NC} = \) moment inertia of the nomcomosite steel section (in.\(^4\))

\( I_0 = \) moment inertia of a cross section about its CG (in.\(^4\))

\( I_{LT} = \) moment of inertia of the transformed long-term composite section (in.\(^4\))

\( I_{ST} = \) moment of inertia of the transformed short-term composite section (in.\(^4\))

\( I_t = \) moment of inertia for the transverse stiffener taken about the edge in contact with the web for single stiffeners and about the mid-thickness of the web for stiffener pairs (in.\(^4\))

\( I_x = \) moment of inertia of the section about the x-x axis (in.\(^4\))

\( I_{x-x} = \) moment of inertia of the section about the x-x axis (in.\(^4\))

\( I_y = \) moment of inertia of the section about the y-y axis (in.\(^4\))
$I_{yc} = \text{moment of inertia of the compression flange about the vertical axis in the plane of web (in.}^4\text{)}$

RDC1 = support force due to the factored permanent load DC1 (kip)

RDC2 = support force due to the factored permanent load DC2 (kip)

RDW = support force due to the factored permanent load DW (kip)

Rh = hybrid factor

R(LL+IM)HL-93 = support force due to factored live load HL-93 (kip)

R(LL+IM)P15 = support force due to factored live load P15 (kip)

Rn = nominal resistance (kip)

Rp = reduction factor for hole

Rpc = web plastification factor

Rr = factored resistance (kip)

Ru = support force due to factored loads (kip)

(Rsb)n = nominal bearing resistance for the fitted end of bearing stiffeners (kip)

(Rsb)r = factored bearing resistance for the fitted end of bearing stiffeners (kip)

r = radius of gyration (in.)

rmin = minimum radius of gyration (in.)

rs = radius of gyration about the axis normal to the plan of the buckling (in.)

rt = effective radius of gyration for lateral torsional buckling (in.)

rx = radius of gyration about the x-x axis (in.)

ry = radius of gyration about the y-y axis (in.)

rz = radius of gyration about the z-z axis (in.)
\( S \) = girder spacing (in.); elastic section modulus (in.\(^3\))
\( S_{LT} \) = elastic section modulus for long-term composite sections, respectively (in.\(^3\))
\( S_{NC} \) = elastic section modulus for steel section alone (in.\(^3\))
\( S_{ST} \) = elastic section modulus for short-term composite section (in.\(^3\))
\( S_{xt} \) = elastic section modulus about the major axis of the section to the tension flange taken as \( M_{yt}/F_{yt} \) (in.\(^3\))
\( s_r \) = shear flow resistance of the weld (kip/in.)
\( s_u \) = resultant force on the weld (kip/in.)
\( t_f \) = thickness of the flange (in.)
\( t_{fc} \) = thickness of a compression flange (in.)
\( t_{ht} \) = thickness of a tension flange (in.)
\( t_p \) = thickness of a projecting stiffener element (in.)
\( t_w \) = thickness of web; weld size (in.)
\( t_s \) = thickness of concrete deck slab (in.)
\( U_{bs} \) = reduction factor for block shear rupture
\( U \) = reduction factor to account for shear lag
\( V \) = design 3-second gust wind speed (mph)
\( V_{cr} \) = shear-buckling resistance (kip)
\( V_{DC1} \) = shear due to the factored permanent load \( DC1 \) (kip)
\( V_{DC2} \) = shear due to the factored permanent load \( DC2 \) (kip)
\( V_{DW} \) = shear due to the factored permanent load \( DW \) (kip)
\( V_{f} \) = factored fatigue vertical shear force range (kip)
\( V_{(LL+IM)HL-93} \) = shear due to factored live load HL-93 (kip)
\( V_{(LL+IM)P15} \) = shear due to factored live load P15 (kip)
\( V_n \) = nominal shear resistance (kip)
\( V_p \) = plastic shear force (kip)
\( V_r \) = factored shear resistance of welds (kip)
\( V_{sr} \) = range of horizontal shear flow (kip)
\( V_u \) = shear due to the factored loads (kip)
\( WS \) = wind load on structures
\( WS_{bf} \) = wind load acting on the bottom flange (kip/ft)
\( WS_{girder} \) = wind load acting on the girder span (kip/ft)
\[ WS_{tf} = \text{wind load acting on the top flange (kip/ft)} \]
\[ y_c = \text{distance between the bottom flange and CG of concrete deck slab (in.)} \]
\[ y_{LTb} = \text{distance between the bottom flange and CG of long-term composite sections (in.)} \]
\[ y_{LTt} = \text{distance between the top flange and CG of long-term composite sections (in.)} \]
\[ y_{NCCb} = \text{distance between the bottom flange and CG of noncomposite steel sections (in.)} \]
\[ y_{NCTt} = \text{distance between the top flange and CG of noncomposite steel sections (in.)} \]
\[ y_{STb} = \text{distance between the bottom flange and CG of short-term composite sections (in.)} \]
\[ y_{STt} = \text{distance between the top flange and CG of short-term composite sections (in.)} \]
\[ y_i = \text{distance between component CG and the bottom of the bottom flange (in.)} \]
\[ \bar{Y} = \text{distance from the plastic neutral axis to the top of the element where the plastic neutral axis is located (in.)} \]
\[ Z_r = \text{shear fatigue resistance of an individual shear connector (kip)} \]
\[ \gamma = \text{the ratio of } A_f \text{ to } A_p \text{ for filler plate design} \]
\[ \gamma_i = \text{load factor} \]
\[ \lambda_{pw(Dc)} = \text{limiting slenderness ratio for a compact web corresponding to } 2D_c/t_w \]
\[ \lambda_{pw(Dcp)} = \text{limiting slenderness ratio for a compact web corresponding to } 2D_{cp}/t_w \]
\[ \lambda_f = \text{slenderness ratio for compression flange} = b_{fc}/2t_{fc} \]
\[ \lambda_{pf} = \text{limiting slenderness ratio for a compact flange} \]
\[ \lambda_{rf} = \text{limiting slenderness ratio for a noncompact flange} \]
\[ \lambda_{rw} = \text{limiting slenderness ratio for a noncompact web} \]
\[ \gamma_i = \text{load factor} \]
\[ \rho_t = \text{larger of } F_{yw}/F_{crs} \text{ and } 1.0 \]
\[ \eta_D = \text{ductility factor} \]
\[ \eta_i = \text{load modifier factor} \]
\[ \eta_R = \text{redundancy factor} \]
\[ \eta_I = \text{operational factor} \]
\( (\Delta F)_{TH} \) = constant-amplitude fatigue threshold (ksi)

\( (\Delta F)_n \) = fatigue resistance (ksi)

\( \phi_b \) = resistance factor for bearing on milled surfaces

\( \phi_{bb} \) = resistance factor for bolt bearing on material

\( \phi_{bs} \) = resistance factor for block shear rupture

\( \phi_c \) = resistance factor for axial compression

\( \phi_{e2} \) = resistance factor for shear in throat of weld metal in fillet weld

\( \phi_f \) = resistance factor for flexure

\( \phi_s \) = resistance factor for bolts in shear

\( \phi_{sc} \) = resistance factor for shear connector

\( \phi_u \) = resistance factor for tension, fracture in net section

\( \phi_v \) = resistance factor for shear

\( \phi_y \) = resistance factor for tension, yielding in gross section
