Large-scale and Long-term Forecasting of Performance Measurement of Public Transportation Systems

To develop a machine learning approach for large spatial scale and long-term performance measurement forecasting for public transportation systems.

WHAT IS THE NEED?

Reliable long-term forecasting of performance measurement for public transportation systems over a large area is essential for policymakers to achieve effective city planning as well as promotes ridership. For example, forecasting bus arrival time for the next day helps a rider to plan their commute early. Existing approaches typically rely on traffic simulation tools and models that require expert knowledge to execute and adjust parameters for various traffic scenarios.

Previously under a Caltrans funded project, the researchers developed a data-driven, deep learning approach for traffic flow prediction and bus arrival time estimation. The researchers also built a system that uses the traffic predictions for forecasting various performance metrics for public transportations in Los Angeles (e.g., bus arrival times). The system demonstrates the overall approach in an area near downtown Los Angeles and shows that incorporating traffic flow predictions can help to forecast short-term bus arrival times accurately (e.g., in the next few hours).

WHAT ARE WE DOING?

The researchers plan to build on their current approach and system to develop the capability for processing the entire Los Angeles Metropolitan Area (and extendable to the entire state) for long-term forecasting (e.g., days instead of hours) of a variety of public transportation system performance metrics. The major challenges include:
1. How to predict/infer traffic speed on a road segment when there is no traffic sensor at the road segment,
2. How to overcome the computational and memory bottlenecks of training a deep learning network for traffic flow forecasting over a large road network, and
3. How to deal with the large error propagation in the deep learning network for forecasting over a long-time span.

This research will explore both spatial statistical methods and machine learning methods for the estimation of traffic speed for the road segments that do not have a traffic sensor. The researchers will investigate methods to represent large road networks into a condensed graph or multiple subgraphs so that the deep learning network can scale to process large spatial areas. They will also study various training methods and network architectures (e.g., teacher forcing) to enable long-term forecasting of both traffic flows and the performance measurement of public transportation systems.

WHAT IS OUR GOAL?

To demonstrate the results from the proposed research, the researchers will develop a web application in which users can select the start time of a trip and access the predicted bus arrival times anywhere in the entire Los Angeles Metropolitan Area. This research will exploit real-world big traffic sensor data and California Highway Patrol accident logs collected from the Regional Integration of Intelligent Transportation Systems in the last nine years under the existing Archived Traffic Data Management System project.

WHAT IS THE BENEFIT?

Results from this project will help Caltrans’ Transportation Planning Division and other policymakers by giving them a tool to improve transit planning. This tool will also assist Caltrans reaching its System Performance goals.

WHAT IS THE PROGRESS TO DATE?

1. The researchers identified and tested an approach to scale up our deep learning traffic prediction model to handle the entire Los Angeles area. Specifically, they split the sensor network in Los Angeles into small graphs and train a deep learning model for each graph. They then showed that this approach can generate accurate traffic forecasting results for the entire Los Angeles area when sensors are available.
2. The researchers compared several approaches for recovering missing data from the traffic sensors in Archived Data Management System using comprehensive experiment settings (e.g., random missing data vs. long time missing data). The recovered data will be used to train the traffic forecasting model and in turn, help predicting the bus arrival time. The research has identified the best approach for the goal of predicting long-term bus arrival time using traffic forecasting data.
