MMITSS Phase III Extension for Additional Enhancements

A research project by UC Berkeley PATH program to add traffic adaptive and multimodal aspect enhancements to Multi-Modal Intelligent Traffic Signal System (MMITSS) for improved mobility and safety.

WHAT IS THE NEED?

The Multi-Modal Intelligent Traffic Signal System (MMITSS) is the next generation of traffic signal systems that seeks to provide a comprehensive traffic information framework to service all modes of transportation, including general vehicles, transit, emergency vehicles, freight fleets, pedestrians and bicyclists in a connected vehicle environment.

Under the sponsorship of the Connected Vehicle Pooled Fund Study (CV PFS) and Federal Highway Administration (FHWA), MMITSS has been deployed in the California CV Test Bed. Caltrans Statewide Traffic Signal Control Program (TSCP) has been enhanced to support MMITSS operations, including:

- Signal Phase and Timing (SPaT) broadcasts
- CV-based vehicular service calls and actuations
- Pedestrian service calls
- CV-based signal priority
- Dynamic force-off (to adapt signal timing to the prevailing traffic conditions)

The current coordinated traffic control systems utilize a few time-of-day timing plans (cycle length, green split, and offset) for time-based coordination and utilize loop detectors for phase service calls and vehicle actuations. The time-of-day timing plans are preset based on traffic data collected through site surveys. Inductive loops are usually installed near the intersection stop-line and cannot detect and measure the fluctuation of traffic demand in real-time. Therefore, the traffic control systems are not

DRISI provides solutions and
knowledge that improves
California's transportation system

well informed about the state of the traffic and are unable to select the appropriate timing plan that adapts to the prevailing traffic conditions. Furthermore, in the current systems, pedestrian service requests are detected by pedestrian pushbuttons, but the systems are not necessarily aware of how many pedestrians use the buttons and their location on the crosswalk.

In a CV environment where equipped vehicles and pedestrians communicate their state (type, location, speed, heading, etc.) to the roadside infrastructure via Basic Safety Messages (BSM – vehicle) and Personal Safety Messages (PSM – pedestrian), this rich data set allows the traffic control systems to measure the fluctuation of traffic demand in real-time, adapt timing plan to the prevailing traffic conditions, and provide cooperative services to each mode.

Although the anticipated benefits of CV technologies on improving safety and mobility are promising, due to the low market penetration rate of connected vehicles, the benefits of CV technologies are difficult to assess in a real-world condition.

WHAT ARE WE DOING?

The objectives of this project are:

- 1. Enhance Traffic Control Features:** Utilize multimodal road user detection and classification data (e.g., vehicles, pedestrians, and bicyclists) of NoTraffic Smart Sensors and adaptive signal timing features of the existing TSCP to add additional enhancements to MMITSS for improved mobility and safety;
- 2. Enhance the Deployability of MMITSS Vehicle-Resident Applications:** Modularize the existing vehicle-resident CV application software and develop an application programming interface (API) to support a hardware-agnostic solution. The API will support the use of OBUs from multiple vendors.
- 3. Conduct Field Testing with Augmented**

Market Penetration: Field testing will comprise both equipped VTA buses and PATH testing vehicles. PATH testing vehicles will collect the ground-truth travel time and delay data, which provide inputs to the before-and-after analysis on impacts of market penetration.

WHAT IS OUR GOAL?

The goal of this project is to add traffic adaptive and multimodal aspect enhancements to MMITSS for improved mobility and safety.

WHAT IS THE BENEFIT?

The research study will assist the State of California to do the following:

- Better assess the effectiveness of traffic adaptive features that support multimodal transport
- Better assess the impacts of market penetration of CVs
- Provide better safety and mobility for all modes of travel

WHAT IS THE PROGRESS TO DATE?

The project has been executed and will start on June 29, 2020.
